## PREFACE TO FIRST EDITION

THE need for a set of up-to-date English physical and chemical tables of convenient size and moderate price has repeatedly impressed us during our teaching and laboratory experience. We have accordingly attempted in this volume to collect the more reliable and recent determinations of some of the important physical and chemical constants.

To increase the utility of the book, we have inserted, in the case of many of the sections, a brief resume containing references to such books and original papers as may profitably be consulted.

Every effort has been made to keep the material up to date ; in many cases a fult reference to the original paper is given, while, failing such reference, the year of publication is almost always indicated.

The scope of the volume calls for little comment on our part. We have dipped a little into Astronomy, Engineering, and Geology in so far as they border on Physics and Chemistry. It will be noticed that considerable space has been allotted to Radioactivity and Gaseous Ionization : it is hoped that the collection of data, which we believe to be the first of the kind, will be of assistance to the numerous workers in a field whose phenomenal and somewhat transitional growth is a little dismaying from our present point of view.

Attention has been paid to the setting and accuracy of the mathematical tables; these are included merely to facilitate calculations arising out of the use of the book, and limitations of space have cut out all but a few of the more essential functions. The convenience of the student of the newer physics has been studied by the inclusion of a table of values of $e^{-x}$ reduced from Newman's original results.

We began this book while at the Cavendish Laboratory, Cambridge, and Dr. G. A. Carse shared in its inception. To Mr. G. F. C. Searle, F.R.S., we feel we owe much for his encouragement and suggestions when the scope of the book was under consideration. We record gratefully the help of a number of frien ls who have seen the proof-sheets of sections dealing with subjects with which their names are associated. Dr. J. A. Harker, F.R.S., and Mr. R. S. Whipple read the sections on Thermometry; Mr. F. E. Smith revised the account of Electrical Standards, and Mr. C. C.

Paterson that of Photometry ; Mr. A. Campbell criticized the section on Magnetism ; and Professor Callendar, Principal Griffiths, and Dr. Chree have elucidated various points in Heat and Terrestrial Magnetism.

We owe thanks to Dr. Glazebrook for his permission to utilize the values of a number of constants recently determined at the National Physical Laboratory. Finally, we are greatly indebted to Mr. E. F. F. Kaye, M.Sc., who has given us valuable assistance in preparing the manuscript and revising the proof-sheets.

It was decided to keep the volume within reasonable limits, partly for the reader's convenience, and partly with the hope that the task of subjecting it to frequent revision in the future might not be impossible. We have consequently had to pick and choose our data, and it is scarcely likely that our selection will meet every individual requirement. That some sections are inadequately treated we fully realize, and we shall be very glad to receive suggestions and to be informed of any mistakes which, despite every care, have eluded us.

G. W. C. K.<br>T. H. L.

September, 19 II.

## PREFACE TO SECOND EDITION

WE regret that the difficulties of the times have not permitted the complete revision which we had contemplated. We have had to content ourselves with removing those mistakes of which, by the courtesy of many readers, we had become aware, and inserting a number of the more fundamental constants which contemporary research has yielded since 1911. A few tables have been thoroughly revised.

> G. W. C. K.
> T. H. L.

September, 1916.

## PREFACE TO THIRD EDITION

In the few months that have elapsed since the publication of the last edition, we have not found it possible to do more than bring a few primary constants up to date.

G. W. C. K.<br>T. H. L.

## C.G.S. UNITS AND DIMENSIONS

References: Mach, "Science of Mechanics;" Everett, "C.G.S. System of Units;" Maxwell "Theory of Heat."

The metric standards of length and mass are kept at the International Bureau of Weights and Measures in the Pavillon de Breteuil, Sèvres, near Paris. The Bureau is jointly maintained by the principal civilized governments as members of the Metric Convention. The use of metric weights and measures was legalized in the United Kingdom in 1897.

## LENGTH

Unit-the centimetre, $1 / 100$ of the international metre, which is the distance, at the melting-point of ice, between the centres of two lines engraved upon the polished "neutral web" surface of a platinum-iridium bar of a nearly X-shaped section, called the International Prototype Metre.

The alloy of 90 Pt , 10 Ir used (also for the International Kilogramme) has not a large expansion coefficient (see p. 53), is hard and durable, and was artificially aged. Pt-Ir copies of this metre, called National Prototype Metres, were made at the same time, and distributed by lot about 1889 to the different governments. The international metre is a copy of the original Borda platinum standard - the mètre des archives. This was intended to be one tenmillionth of the quadrant from the equator to the pole through Paris, and was legalized in 1795 by the French Republic. But as the value of a quadrant came to be more accurately deternined, and moreover is changing, the actual bar constructed was made the standard.*

The international prototype metre has been measured (1894 and 1907) in terms of the wavelengths of the cadmium rays (see p. 75), and equals $1,553,164 \cdot 1$ wave-lengths of the red ray, in dry air at $15^{\circ}$ C. (H. Scale) and 760 mm . pressure. (See Michelson's "Light Waves," 1903.)

References: Guillaume, "La Convention du Mètre," and Chree, Phil. Mag., 1901.

## MASS

Unit-the gramme, $1 / 1000$ of the International Prototype Kilogramme, which is the mass of a cylinder of platinum-iridium.

The international kilogramme is a copy of the original Borda platinum kilogramme-the kilogramme des archives-which was intended to have the same mass as that of a cubic decimetre of pure water at the temperature of its maximum densily. More exact measurements revealed the incorrectness of the relation (see p. 10), and so the kilogramme was subsequently defined as above.

As with the metre, Pt-Ir copies of the international standard-National Prototype Kilo-grammes-have been distributed to the different governments.

## tIME

Unit-the second, which may be defined simply as $1 / 86,164 \% 0$ of a sidereal day. For all practical purposes the sidereal day may be regarded as the period of a complete axial rotation $\left(360^{\circ}\right)$ of the earth with respect to the fixed stars. $\dagger$

The second is usually defined as $1 /(24 \times 60 \times 60)$ of a mean solar day, i.e. $1 / 86,400$ of the average value of the somewhat variable interval (the apparent solar day) between two successive returns of the sun to the meridian (see p. 15).

Strictly, the sidereal day is the interval between two successive transits of the first point of Aries $\ddagger$ across any selected meridian.§ The true period of rotation of the earth is actually about $1 / 100$ second longer than the sidereal day ; the difference arises from the slow and continual change of direction ("precession") of the earth's axis in space.

A tropical or solar year is the average interval between two successive returns of the sun to the first point of Aries; it is found to equal $365^{\prime 2} 2 \mathbf{N}^{22}$ mean solar days. Our modern (Julian) calendar assumes that in 4 successive civil years, 3 consist of 365 days, and 1 of 366 ; the average thus being $365^{\circ 25}$ days. The Gregorian correction (that century years are not to count as leap years unless divisible by 400 ) reduces this value to $365^{\circ} 2425$ mean solar days, and thus the average civil year is a close approximation to a tropical year.

[^1]
## BRITISH UNITS

A sidereal year is the time interval in which the sun appears to perform a complete revolution with reference to the fixed stars ; ie. it is the time in which the earth describes one sidereal revolution round the sun. Owing to precession, a sidereal year is longer than a tropical year.
h. m. s.
Mean solar day $=24 \quad 0 \quad 0 \quad=86,400 \mathrm{secs}$.
Sidereal day $=2356 \quad 4^{\circ 0906}=86,164^{\circ} 0906$ secs.
Tropical year $=j 6 ; 2422$ mean solar days.
Sidereal year $=36.2564 \quad$, $\quad$ " (epoch 1900).
$=366.2564$ sidcreal days.

Reference : Newcomb, "'Astronomy."

## BRITISH IMPERIAL STANDARDS.

(From information supplied by Major MacMahon, F.R.S., Board of Trade, Standards Office.)
According to the Weights and Measures Act, 1878, the yard is the distance, at $62^{\circ} \mathrm{F}$., between the central transverse lines in two gold plugs in the bronze bar, called the Imperial Standard Yard, when supported on bronze rollers in such manner as best to avoid flexure of the bar.

The defining lines are situated at the bottom of each of two holes, so as to be in the median plane of the bar, which is of 1 inch square section and $3^{3}$ inches long. Its composition is 32 Cu , $5 \mathrm{Sn}, 2 \mathrm{Zn}$. Copper alloys are now known not to be suitable for standards of length, and in 1902 a Pt -It X -shaped copy of the yard was made.

The pound is the weight in vacuo of a platinum cylinder called the imperial standard pound.

The imperial standard yard and pound are preserved at the Standards Office of the Board of Trade, Old Palace Yard. A number of official copies have been prepared, and are in the custody of the Royal Society, the Mint, Greenwich Observatory, and the Houses of Parliament.

The gallon contains 10 lbs . weight of distilled water weighed in air against brass weights at a pressure of 30 inches, and with the water and the air at $62^{\circ} \mathrm{F}$.
[NOTE.- No mention is made in the Act of the density of the brass weights, or of the humidity of the air.]

## BRITISH AND METRIC EQUIVALENTS

The present legal equivalents are those legalized by the Order in Council of May 19, 1898, and derived at the International Bureau of Weights and Measures, by Benoit in 1895 in the case of the yard and the metre, and by Broch in 1883 for the pound and the kilogramme. (See Trav. et Mém. du Bur. Intl., tomes iv., 1885, and xii., 1902.)

Imperial Standard.

$$
\begin{array}{ll}
1 \text { yard } & = \\
1 \text { pound } & = \\
414399 \text { metre }
\end{array}
$$

(Reciprocal.)
1.093614

2:2046223
[NOTE.-The yard is defined at $62^{\circ} \mathrm{F}$., the metre at $0^{\circ} \mathrm{C}$.]

## DERIVED C.G.S. UNITS AND STANDARDS

 GENERAL AND MECHANICAL UNITS
## Area:-Unit-the square centimetre.

Volume :-Unit-the cubic centimetre (c.c.). The metric unit is the litre, now defined as the volume of a kilogramme of pure, air-free water at the temperature of maximum density (see p. 22) and 760 mm . pressure (Procès Verbaux, 1901, p. 175). The litre was originally intended to be 1 cubic decimetre or 1000 c.cs. ; the present accepted experimental relation is that I kilogramme of water at $4^{\circ} \mathrm{C}$. and 760 mm . pressure measures 1000.027 c.cs. (see p. 10).

Density :-Unit-grammes per c.c. Specific gravity expresses the density of a substance relative to that of water, and is objectionable in requiring two temperatures to be stated.
Velocity :-Unit-I cm. per second. Angular Velocity :-Units-I radian ( $57^{\circ}$ 296) per sec. ; I revolution per sec.
Acceleration :-Time rate of alteration of velocity. Unit- ( Icm. per sec.) per sec. Angular Acceleration :-Units-I radian per sec. ${ }^{2}$; 1 revolution per sec. ${ }^{2}$ Momentum :-Mass multiplied by velocity. Unit-1 gm. $\mathrm{cm} . \mathrm{sec}^{-1}$.
Moment of Momentum :- Momentum multiplied by distance from axis of reference. Unit-1 cm. $2^{2} \mathrm{gm} . \mathrm{sec}^{-1}$.
Moment of Inertia:- $\mathrm{E}^{2} \mathrm{a}^{2}$, where $m$ is the mass of any particle of a body, and $d$ it distance from the axis of reference. Unit-1 $\mathrm{cm} .^{2} \mathrm{gm}$. (see p. 16).
Angular Momentum :- Moment of inertia multiplied by angular velocity round axis of reference. Unit- $1 \mathrm{~cm} .^{2} \mathrm{gm}$. sec..$^{-1}$.
Force:-Measured by the acceleration it produces in unit mass. C'nit-the dyne $=\mathrm{cm} . \mathrm{gm} . / \mathrm{sec}^{2}{ }^{2}$ Gravitational minit-the weight of I gram $=\sigma$ dsncs.
Couple, Torque, Turning Moment:-Force multiplied by distance from point of reference. Unit-1 dyne cm .
Work:-Force multiplied by distance through which point of application of force moves in direction of force. Unit-the erg $=1$ dyne $\mathrm{cm} . ; \mathrm{I}$ joule $=10^{7}$ ergs. [r calorie $=4 \cdot 18$ jouies]. Gravitational unit-weight of $1 \mathrm{gm} . \times 1 \mathrm{~cm} .=g$ dyne $\mathrm{cms}=$.$g ergs.$
Energy:-Measured by the work a body can do by reason of either ( r ) its motion-Kinetic Energy ( $=m \nu^{2} / 2$ ) or (2) its position-Potential Energy. Unit-the erg. (See "Work.") I Board of Trade Unit = I kilowatt hour = $3^{.6} \times 10^{6}$ watt-secs.
Power:-Work per unit time. Unit-1 erg per sec. I watt $=10^{7} \mathrm{ergs}$ per sec. $=\mathrm{I}$ joule per sec. $=\mathrm{I}$ volt-amifere. I kilowatt $=\mathrm{r} \cdot 3 \dagger$ horse-power.
Pressure, Stress:-Force per unit area. Unit-1 dyne per cm. ${ }^{2} 1$ megabar $=10^{\circ}$ dynes per cm. $.^{2}=750^{*} \mathrm{~mm}$. mercury at $0^{\circ} \mathrm{C}$., lat. $45^{\circ}$, and sea-level $(g=9806)$. I atmosphere $=760 \mathrm{~mm}$. mercury at $\circ^{\circ} \mathrm{C}$., lat. $45^{\circ}$, and sea-level $=750^{\circ} 4 \mathrm{~mm}$. mercury at $0^{\circ} \mathrm{C}$. in London $=\mathrm{r}^{\circ} \mathrm{O}_{3} 2 \times 10^{6}$ dynes per $\mathrm{cm} .^{2}=14^{\prime} 7 \mathrm{lbs}$. per inch ${ }^{2}$ $=0.94$ ton per foot ${ }^{2}$.

- Correct to 1 part in 5000 .

Elasticity :-Ratio of stress to resulting strain. Unit-I dyne per $\mathrm{cm} .^{2}$, since the dimensions of a strain are zero.

## HEAT UNITS

Temperature :-The melting-point of pure ice under 1 atmosphere is defined as $0^{\circ} \mathrm{C}$., and the boiling-point of water under I atmosphere as $100^{\circ} \mathrm{C}$. This fundamental interval is divided into 100 parts by use of the constant-volume hydrogen thermometer (see p. 44) ; each part is a degree Centigrade. Dimensions of temperature are not required, as it is defined independently of mass, length, and time.

Heat :-Dynamical unit-the erg. Thermal unit-the calorie $=$ heat required to raise the temperature of I gramme of water from $t^{\circ} \mathrm{C}$. to $(t+1)^{\circ} \mathrm{C}$. The $20^{\circ}$ calorie $\left(t=20^{\circ}\right)=4.180 \times 10^{7}$ ergs. The $15^{\circ}$ calorie $\left(t=15^{\circ}\right)=4.184 \times$ $10^{7}$ ergs. The mean calorie ( $=1 / 100$ heat required to raise I gramme of water from $0^{\circ}$ to $100^{\circ}$ C.) $=4.184 \times 10^{7}$ ergs. (see pp. 55; 56). I watt-minute $=14^{\circ} 3$ calories. The large calorie $=1000$ calories.

Gas Constant R., in $p v=\mathrm{R} \theta / m$, where $p$ is the pressure, $v$ the volume, $\dot{\theta}$ the absolute temperature of a gram-molecule (i.e. $m$ grams) of a gas of molecular weight $m$. For I gram-molecule of an ideal gas of density $p$, $\mathrm{R}=\frac{p v^{\prime} \eta l}{\theta}=\frac{p}{\theta} \cdot \frac{112}{\rho}=\frac{1.0132 \times 10^{6} \times 22412}{273^{\circ} 1}=8.15 \times 10^{6} \mathrm{ergs}$ per gnm. mol. (Berthelot, see $p$. 106). This value is a constant for all ideal gases. To derive $R$ for I gram of a gas, this figure should be divided by the molecular "eight (oxygen =16) of the gas. $R$ has the dimensions of a specific heat in dynamical units.

## ELECTRICAL AND MAGNETIC UNITS

Reference:-J. J. Thomson, "Mathematical Theory of Electricity and Magnetism." The fundamental basis of the electrostatic system of units is the repulsive force between two quantities of like electricity. In the electromagnetic system the repulsion between two like magnetic poles is taken as the basis.

The electromagnetic system (or one based on it) is universally employed in electrical engineering ; the electrostatic is used only in certain special cases.

## electrostatic units

Quantity or Charge:-Unit-that quantity which placed I cm. distance from an equal like quantity repels it with a force of I dyne.

Current:-Unit-Unit quantity flowing uniformly past a point in unit time.
Potential Difference and Electromotive Force:-Unit-that P.D. which exists between two points when the work done in taking unit quantity from one point to the other is I erg.

Capacity :-Unit-the charge on a conductor which is at unit potential ; or in the case of a condenser, when its plates are at unit P.D.

Dielectric Constant, Inductivity, or Specific Inductive Capacity of a medium is the ratio of the capacity of a condenser having the medium as dielectric, to the capacity of the same condenser with a vacuum as dielectric (p.84).

## ELECTROMAGNETIC UNITS

Magnetic Pole Strength or Quantity :-Unit-that quantity which, placed 1 cm . distance from an equal like quantity, repels it with a force of I dyne.

Magnetic Force or Field Strength:-Unit-the force which acts on unit magnetic pole.

Magnetic Moment of magnet $=$ pole strength $\times$ length of magnet.
Intensity of Magnetization = magnetic moment per unit volume.
Permeability of a medium is the ratio of the magnetic induction in the medium to that in the magnetizing field (p. 89).

Susceptibility:-Unit-intensity of magnetization per unit field (p. 89).
Electric Current:-Unit-that current which produces unit magnetic force at the centre of a circle of radius $2 \pi \mathrm{cms}$.

Quantity $=$ current $\times$ time .
Potential and E.M.F. :-Unit-that P.D. which exists between two points when the work done in taking unit quantity from one point to the other is I erg.

Electrostatic Capacity = quantity/potential difference.
Resistance = potential difference/resulting current. (Ohm's law is assumed.)
Conductance:-Reciprocal of resistance.
Specific Resistance :-Resistance of prism of unit area and unit length.
Conductivity:- Keciprocal of specific resistance.
Coefficient of Self-induction of a circuit is the E M.F. produced in it by unit time-rate of variation of the current through it.

Coefficient of Mutual Induction of two circuits is the E.M.F. produced in one by unit time-rate of variation of the current in the other.

## PRACTICAL ELECTRICAL UNITS

At an International Conference on Electrical Units and Standards held in London, October, 1908, it was resolved that-
I. The magnitudes of the fundamental electrical units shall, as heretofore, be determined on the electromagnetic system of measurement with reference to the centimetre, gramme, and second (c.g.s.). These fundamental units are (i) the $\mathbf{O h m}$, the unit of electrical resistance, which has the value $10^{9}$ c.g.s. ; (2) the Ampere, the unit of electric current, which has the value $10^{-1} \mathrm{c} . \mathrm{g.s}$. : (3) the Volt, the unit of electromotive force, which has the value $10^{8}$ c.g.s. ; (4) the Watt, the unit of power, which has the value $10^{7}$ c.g.s. [For absolute electrical units, see p. 8.]
2. As a system of units representing the above, and sufficiently near to them to be adopted for the purpose of electrical measurements, and as a basis for legislation, the Conference recommends the adoption of the International Ohm, the International Ampere, and the International Volt.
3. The Ohm is the first primary unit. The Intermational Ohm is defined as the resistance offered to an unvarying electric current by a column of mercury at $0^{\circ}$ C., 14.452 I grammes in mass, of a constant cross-section, and of a length of 106.300 cms .
4. The Ampere is the second primary unit. The International Ampere is defined as the unvarying electric current which, when passed through a solution of nitrate of silver in water, in acco:dance with authorized specification, deposits silver at the rate of ool11800 gramme per second.
5. The International Volt is defined as the electical pressure which, when steadily applied to a conductor whose resistance is one International Ohm, will produce a current of one International Ampere.
6. The International Watt is defined as the energy expended per second by an unvarying electric current of one International Ampere under an electric pressure of one International Volt.

## DIMENSIONS OF UNITS

The dimensions in terms of length, mass, and time are denoted by the indices given under L, M, and T. Thus the dimensions of power are $\mathrm{L}^{2} \mathrm{MT}^{-3}$.

MECHANICAL AND HEAT UNITS

| Quantity. | L. M. T. | Quantity. | L. M. T. | Quantity. | L. M. T. |

## ELECTRICAL UNITS

## ABSOLUTE DETERMINATIONS OF. ELECTRICAL UNITS

See Baillehache, "Unités Électriques," Paris, 1909, and the "Report of the London Conference" (p.6). The appendix to this report (issued separately, 9 d.) gives full particulars as to the realization of the ampere and ohm, together with the specification of the Weston normal (cadmium) cell.

## THE OHM

The mean value $\mathbf{1 0 6 . 2 5} \mathrm{cms}$. of Hg of $I \mathrm{sq} . \mathrm{mm}$. dross-section at $0^{\circ} \mathrm{C}$. may be taken as a measure of the present experimental value of the true ohm, which is equal to $10^{9}$ E.M. (c.g.s.) units. Compare the international ohm (p.6).

| $\mathrm{cm} . / 0^{\circ}$. | Method. | Observer. | $\mathrm{cm} . / 0^{\circ}$. | Method. | Observer. |

## E.M.F. OF WESTON CELL

The electromotive force (E) of the Weston (cadmium) cell in volts ( $10^{8}$. E.M. units) as realized from one of the accepted specifications. The present accepted international value of E is 1.0183 international volts (see p. 6) at $20^{\circ} \mathrm{C}$.

Temperature coefficient.-Over the range $0^{\circ}$ to $40^{\circ}$, Wolff ( 1908 ) obtained for the E.M.F. at $t^{\circ}$ -

$$
\mathrm{E}_{t}=\mathrm{E}_{20}-0000406(t-20)-9.5 \times 10^{-7}(t-20)^{2}
$$

| E at $20^{\circ}$. | Method. | Observer. | E at $20^{\circ}$. | Method. | Observer. |
| :---: | :---: | :---: | :---: | :---: | :---: |

$\left.\begin{array}{l}\mathbf{N}, \quad m=-000559 \\ \mathbf{H}, \quad m=+000772\end{array}\right\}$ Chappuis, Rayleigh, Leduc, and Sacerdote.

## VALUES OF GRAVITY ("g") LONGITUDE AND LATITUDE

Helmert's formula connecting "gravity" with latitude and height is $g=980.617-2.593 \cos 2 \lambda-.0003086 \mathrm{H}$, where $\lambda$ is the latitude, H is the height in metres above sea-level, and 980.617 cms . $/ \mathrm{sec} .^{2}$ is the value of $g$ attributed to lat. $45^{\circ}$ and sea-level. The values of $g$ calculated by this formula are for most places in fair agreement with the observed values. Some discrepancy is found in the vicinity of large mountain ranges, such as the Himalayas.

No absolute standard determination of $g$ has been made in England for many years, but comparisons have been made with Potsdam and Sèvres. For relative measurements, the relation $d y=0226 d \mathrm{~N}$ is useful, where N is the number of vibrations which a pendulum makes in a mean solar day of 86,400 mean time seconds. The length ( $l$ ) of the "seconds" pendulum (i.e. 2 secs. period) $=g / \pi^{2}$ $=\cdot 101321 \mathrm{Ig} . l$ varies from $99^{\circ} 09.4 \mathrm{cms}$. at the equator to $99^{\circ} 620 \mathrm{cms}$. at the pole.

See Helmert's "Höhere Geodäsie," "Die Grösse der Erde," 1906, and "Die Schwerkraft im Hochgebirge," Clarke's "Geodesy," 1880, Sir Geo. Darwin's "Tides and Kindred Phenomena," Fisher's "Physics of the Earth's Crust," and for recent aspects of the subject, the reports to the triennial International Geodetic Conferences (...1906, 1909...), and the reports of the U.S. Geodetic Survey. (See also p. 13.)

light to travel from $=498^{\circ} 2$ secs. sun to earth

MOON
Mean distance from $\}=\left\{60^{\circ} 27 \times\right.$ earth's earth to moon $\}=\{$ radius
Mass of the moon $\}=\{(1 / 81 \cdot 53) x$ (Hinks, 1909) $\}=\{$ earth's mass Inclination of moon's orbit to ecliptic $\}=5^{\circ} 8^{\prime} 43^{\prime \prime}$

Constant of Gravitation (G in law of attraction) $=6.658 \times 10^{-8}$ c.g.s.

Obliquity of the Ecliptic to the equator $=23^{\circ} 27^{\prime} 4^{\prime \prime} \circ 4$ in 1909, subject to a small fluctuation by nutation, and a slow continuous decline of $46^{\prime \prime \prime} 84$ per century.

Constant of aberration of a star is theoretically equal to (Earth's orbital velocity)/(velocity of light) $=20^{\prime \prime \prime} 43 \pm " \circ 03$ (Renan and Ebert, 1905).

Constant of precession, i.e. annual precessional increase of the longitude of a star $=50^{\prime \prime} \cdot 2564+{ }^{\prime \prime} \cdot 0002225 t$, where $t$ is the interval in years from 1900 (Newcomb).

## ELEMENTS OF THE SOLAR SYSTEM

$8^{\prime \prime} \cdot 806$ is taken as the equatorial horizont 11 solar parallax from the observations of the as eroid Eros in 1900-1 ; 5.527 is adopted as the Earth's mean density (Boys, 1895 ; Braun, 1896). The constants for Mercury are those adopted by Stroobant and Backland (1909). The value of the mass of Jupiter is that obtained by Cookson (1908). The time of rotation of Venus is that suggest•d by Hansky and Stefánik (1907). (See Newcomb's "Spherical Astronomy"and Bill's "Spherical Astronomy.")

## EQUATION OF TIME

$(+)$ means that the equation of time has to be added to the apparent solar time (i.e. sundial time) to give the mean solar or clock time (see p. 3). (M) = maximum or minimum. The values below vary by a few seconds from year to ycar. $C=D+E$, where $C=$ clock time, $D=$ dial time, and $E=$ equation of time.

| Date. | Equation of time. | Date. | Equation of time. | Date. | Equation of time. | Date. | Equation of time. |

## PARALLAXES OF STARS

The proper motion of a star is its real change of place arising from the actual motion of the star itself.

The annual parallax is the angle between the direction in which a star appears as seen from the earth and the direction in which it would appear if it could be observed from the centre of the sun.

A light-year is the distance that light travels in one year (see p. 69).

| Star and Magnitude. | Proper motion per year. | Annual parallax. | Distanee. |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Sun's dist. $=1$ | Light-years. |

## SCREWS

It is customary for British metal screws; of $\frac{1}{1}$-inch diameter and above, to have a Whitworth thread, for smaller sizes a British Association thread. In the Whitworth thread the angle between the slopes is $55^{\circ}$, in the B.A. thread $47^{\circ} 5^{\circ}$.

The pitch is the distance between adjoining crests (say) of the same thread measured parallel to the axis of the screw. It is the reciprocal of the number of turns per inch or mm . as the case may be. The full diameter is the maximum over-all diameter.

Mricrometer screws are made with some multiple or sub-multiple of 100 threads to the inch or mm .
"Woodscrew3" of iron or brass are numbered as follows: No. o has a diameter of os inch, each succeeding number adding o14 inch to the diameter of the screw : this applies to all lengths. The length of countersunk screws is measured over all ; that of round-headed screws, from under the head.
[ I inch $=25.4 \mathrm{~mm}$.]

## VOLUME CALIBRATION OF VESSELS BY WATER OR MERCURY

Volume content of vessel at $t^{\circ} \mathrm{C} .=\mathrm{V}_{t}=\mathrm{W}_{t} v_{t} \equiv \tau v_{t}(f)$, where-
$v_{t}=$ observed weight in grams (against brass weights in air) of contained water (or mercury) at $t^{\circ} \mathrm{C}$.
$\mathrm{W}_{t}=$ weight of such liquid in vacun (i.e. corrected for buoyancy in air).
$v_{t}=$ volume of I gram of liquid at $t^{\circ} \mathrm{C}$.
$(f)$ is a factor which introduces the buoyancy and specific volume corrections.
The following table of values of the factor $(f)$ is based on tables on pp .19 and 22.

| Temp. ( $t$ ) of weighing | $10^{\circ} \mathrm{C}$ | $11^{\circ}$ | $12^{\circ}$ | $13^{\circ}$ | $14^{\circ}$ | $15^{\circ}$ | $16^{\circ}$ | $17^{\circ}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Value of $\left\{\mathbf{H}_{2} \mathbf{O}\right.$. factor ( $f$ ) $\mathbf{H g}$. | $\left\|\begin{array}{l} 1.00133 \\ \cdot 073683 \end{array}\right\|$ | $\begin{aligned} & 1 \cdot 00143 \\ & 3 \cdot 073697 \\ & \text { I } \end{aligned}$ | $1.0015+$ $073710$ | $\left\lvert\, \begin{aligned} & 1 \cdot 00166 \\ & \because 073724 \end{aligned}\right.$ | $\begin{array}{r} \text { r.00179 } \\ \cdot 073737 \end{array}$ | $\begin{aligned} & 1.00193 \\ & 0 \\ & 073750 \end{aligned}$ | $\left\lvert\, \begin{aligned} & \mathrm{r} \cdot 00209 \\ & \cdot 073764 \end{aligned}\right.$ | $\begin{aligned} & 1 \cdot 00226 \\ & \cdot 073777 \end{aligned}$ |
| Temp. ( $t$ ) of weighing | $18^{\circ}$ | $19^{\circ}$ | $20^{\circ}$ | $21^{\circ}$ | $22^{\circ}$ | $23^{\circ}$ | $24^{\circ}$ | $25^{\circ}$ |
| Value of $\left\{\mathrm{H}_{2} \mathrm{O}\right.$ factor ( $f$ ) $\boldsymbol{H} \mathbf{H g}$ | $\left\|\begin{array}{c} 1 \cdot 00244 \\ 0.073790 \end{array}\right\|$ | $\left\lvert\, \begin{aligned} & 1 \cdot 00263 \\ & \cdot 073804 \end{aligned}\right.$ | $\left\|\begin{array}{l} 1 \cdot 00283 \\ \cdot 073817 \end{array}\right\|$ | $\begin{gathered} \mathrm{r} \cdot 00305 \\ \cdot 073831 \end{gathered}$ | $\begin{gathered} \mathrm{r} \cdot 00327 \\ \cdot 073844 \end{gathered}$ | $\left\lvert\, \begin{aligned} & 1 \cdot 00350 \\ & \cdot 073857 \end{aligned}\right.$ | $\begin{aligned} & 1 \cdot 00375 \\ & \cdot 073871 \end{aligned}$ | $\begin{aligned} & 1.00400 \\ & \cdot 073884 \end{aligned}$ |

The above gives the volume content $\mathrm{V}_{t}$ of the vessel at the temperature of weighing, $t^{\circ} \mathrm{C}$. At any other temperature, $t^{\prime}$, the volume $\mathrm{V}_{t^{\prime}}=\mathrm{V}_{t}\left\{\mathrm{I}+\gamma\left(t^{\prime}-t\right)\right\} \equiv \mathrm{V}_{t}(\mathrm{~F})$, where $\gamma$ is the coefficient of cubical expansion of the material of the vessel. Values of the factor (F) for glass vessels ( $\gamma={ }^{\circ} 000025$ ) are tabulated below.

| $\left(t^{\prime}-t\right)$ | $2^{\circ} \mathrm{C}$ | $4{ }^{\circ}$ | $6^{\circ}$ | $8^{\circ}$ | $-2^{\circ} \mathrm{c}$ | $-4$ | $-6^{\circ}$ | $-8^{\circ}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Value of factor | 005 | $1 \cdot 00010$ | 1.00015 | 1.00020 | '99995 | -99990 | '99985 | -99980 |

Example.-Weight of water contained in a vessel at $10^{\circ} \mathrm{C}=10$ gramis: thence volume of vessel at $10^{\circ} \mathrm{C} .=10 \times 1.00133$ c.cs. The same vessel, if of glass, would contain at $16^{\circ} \mathrm{C}$., $10 \times 1^{.001} 33 \times 1^{\circ} 00015=10.014^{8} \mathrm{c} . \mathrm{cs}$.

## CAPILLARITY CORRECTIONS OF MERCURY COLUMNS

The height of the meniscus and the value of the capillary depression depend on the bore of the tubing, on the cleanliness of the mercury, and on the state of the walls of the tube. The correction is negligible for tubes with diameters greater than about 25 mms . The table below gives the amount of the correction (which has to be added to the height) for various diameters of glass tubing and meniscus heights. (Mendelćeff and Gutkowsky, 1877. See also Scheel and Heuse, Ann. d. Phys., 33, 1910.)

| Bore | Height of meniscus in mms. |  |  |  |  |  |  |  | $\begin{aligned} & \text { Bore } \\ & \text { of } \\ & \text { tube. } \end{aligned}$ | Height of meniscus in mms. |  |  |  |  |  |

## REDUCTION OF BAROMETER READINGS TO $0^{\circ} \mathrm{C}$.

Corrected height $H_{0}=H\left\{1-\frac{(\beta-a) t}{(1+B t)}\right\}$, where $H$ and $t$ are the observed height and temperature of the barometer, $\beta=0001818$ (Regnault), the coefficient of cubical expansion of mercury; $\alpha=0000085$, the coefficient of linear expansion of glass, or 0000184 for brass. Hydrogen temperature scale. (After Broch, Inter. Bur. Weights and Measures.)
(In standard English barometry the mercury is reduced to $32^{\circ} \mathrm{F}$., and the scale to $62^{\circ} \mathrm{F}$. In the table below, both are reduced to the ice point.)

| Temp. (t). | Correction in mms. to be subtracted. |  |  |  |  |  |  |  |  |  |

## REDUCTION OF BAROMETER READINGS TO LAT, $45^{\circ}$ AND SEA-LEVEL

It is a convention to take " $g$ " at lat. $45^{\circ}$ and sea-level as the standard value for "gravity." The corrections below resalt from the variation of " $g$ " with latitude and height above sea-level (see p. II). The barometer correction for latitude $=\frac{H_{0}}{760}(C)$, has to be subtracted from the temperature-corrected barometer reading $H_{0}$ for latitudes between $0^{\circ}$ and $45^{\circ}$; and added for latitudes from $45^{\circ}$ to $90^{\circ}$.

| Latitude | $0^{\circ}$ 90 | $85^{5}$ | $10^{\circ}$ 80 | ${ }^{15} 5^{\circ}$ | $70^{\circ}{ }^{\circ}$ | $25^{\circ}$ | $30^{\circ}$ 60 | $35^{\circ}$ $55^{\circ}$ | $40^{\circ}$ 50 | $45^{\circ}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| c | ${ }_{1} \mathrm{mm}$. | 194 | 1.85 | 170 | 1.51 | $1 \cdot 27$ | ${ }^{9} 9$ | $\cdot 67$ | '34* | . 00 |

The correction of the barometer due to diminution of gravity with increasing height above sea-level amounts to about 24 mm . of mercury per 1000 metres above sea-level. The correction has to be subtracted from the observed reading.

## WEIGHINGS: GAS VOLUMES

## REDUCTION OF WEIGHINGS TO VACUO

The buoyancy correction $=\mathrm{M} \sigma(\mathrm{I} / \Delta-\mathrm{I} / \mathrm{p})=\mathrm{M} k$, where M is the apparent mass in grams of the body in air, $\sigma$ is the density of air $(=.0012)$ in grams per c.c., $\Delta$ is the density of the body, $\rho$ is the density of the weights. The correction is true to $4 \%$ for the following limits: 740 mm . press., $1^{\circ}$ to $22^{\circ} ; 760 \mathrm{~mm}$., $8^{\circ}$ to $29^{\circ} ; 780 \mathrm{~mm}$., $15^{\circ}$ to $35^{\circ}$. If the correction is required more accurately, multiply the value of $k$ given below by $\sigma^{\prime} / 0012$, where $\sigma^{\prime}$ is the true dencity of the air for the temp. and press. at the time of the weighing (for $\sigma^{\prime}$, see p. 25). The corrections for quartz weights are the same as for Al. + means cor ${ }^{\mathrm{n}}$. to be added to observed weight.

## DENSITIES OF THE ELEMENTS

Average densities of liquid and solid elements in grams per c.c. at ordinary temperature unless otherwise stated. For gaseous densities see p. 26. The density of a specimen ma depend considerably on its state and previous treatment, e.g. the density of a cast metal
increased by drawing, rolling, or hammering.

| Element. | Density. | Element. | Density. | Element. | Density |
| :---: | :---: | :---: | :---: | :---: | :---: |

## DENSITY DETERMINATION CORRECTIONS

In the determination of the density of a body by weighing in water, the true density (corrected for air buoyancy and water density) is given by $\Delta(D-\sigma)+\sigma$, where $\Delta$ is the uncorrected density of the body, D is the density of the water, and $\sigma$ is the density of the air. The table below gives the correction to be applied to $\Delta$. D is taken as " 9992 (correct to 1 part in 2000 between $10^{\circ}$ and $18^{\circ} \mathrm{C}$., see p. 22) and $\sigma$ as 0012 (sce p. 25). - means that the correction has to be subtracted from $\Delta$. (See Stewart and Gee, "Practical Physics," vol. i.)

| $\Delta$ | Corr. | $\Delta$ | Corr. | $\Delta$ | Corr. | $\Delta$ | Corr. | $\Delta$ | Corr. | $\Delta$ | Corr. |

## DENSITY OF DAMP AIR

The density of damp air may be derived from the expression $\sigma=\sigma_{d}(\mathrm{H}-0.378 p) / \mathrm{H}$, where $\sigma_{d}$ is the density of dry air at a pressure $H$ mms. (see p. 25), H is the barometric height, and $p$ is the pressure of water-vapour in the air.

## HYDROMETERS

Common: Density $=$ degrecs/ 1000 .
Baumé : Density at $15^{\circ}=144.3 /(144.3$ - Baumé degrees $)$.
Twaddell : Density $=1+$ (Twaddell degrees/2co).
Sikes : One degree $=$ a density interval of 002 on the average .

## DENSITY OF WATER

In grams per millilitre.* Pure air-free water under 1 atmos. Temps. on const.-vol. H.scale. Water has a maximum density at $3^{\circ} .98$ (Chappuis, 1897 ; Thiesen, Scheel and Diesselhorst; De Coppet, 1903). The temp. ( $t_{m}$ ) of maximum density at different pressures ( $p$ ), measured in atmos., is given by $t_{m}=3^{\circ} 98-0225(p-1)$.

The specific volume is the reciprocal of the density. For reciprocals, see p.iz6. (See Chappuis, Trav. et Mém. Bur. Intl, 13, 1907.)

For density of ice see p. 21 ; of steam, p. $26 . \quad$ [* 1 litre $=1000^{\circ} 027$ c.cs.]
Density of water at $-10^{\circ}=99815$; at $-5^{\circ}=99930$.

## DENSITY OF DRY AIR AT DIFFERENT TEMPERATURES AND PRESSURES

Grams per c.c.; pressures in mm. of mercury at $0^{\circ} \mathrm{C}$. lat. $45^{\circ} ; g=980.62$ cms. per sec. ${ }^{2}$. These densities are calculated by the expression $\frac{.001293}{(\mathrm{I}+.00367 t)} \cdot \frac{\mathrm{H}}{760^{\prime}}$, where $\cdot 001293$ is due to Leduc, 1898, and Rayleigh, 1893 (p. 26) ; and 00367 to Regnault. For density of damp air, see p. 21.

## DENSITIES OF GASES

Only those gases for which accurate density determinations have been made are included in this table (see also p. 10). Other gases will be found in the table below. For density of air under different temperatures and pressures, see p. 25.

Densities are in grams per litre ( $1000027 \mathrm{c} . \mathrm{cs}$. see p. 10) at $0^{\circ} \mathrm{C}$. under 760 mm . of mercury at $0^{\circ} \mathrm{C}$. and lat. $45^{\circ}\left(g=980^{\circ} 62\right)$, i.e. under a pressure of $1.01323 \times 10^{6}$ dynes per sq. cm .
(After P. A. Guye, Chem. News, 1908.)

| Gas. | Density and Observer. | Accepted density. | Density rel. to 0 |
| :---: | :---: | :---: | :---: |
| Air | I•2927 L. ; I'2928 | $\begin{gathered} \text { Grams litre. } \\ 1: 2928 \end{gathered}$ | 0.90469 |

## ELASTICITIES

Young's Modulus, or Longitudinal Elasticity, E in dynes per sq. cm.
Rigidity, Torsion Modulus, or Shear Modulus, $u$ in dynes per sq. cm .
Volume Eiasticity, Cubic Elasticity, or Bulk Modulus, $k$ in dynes per sq. cm.
Compressibility (cubic), $\mathrm{C}=\mathrm{I} / \mathrm{k}$.
Poisson's Ratio, $\sigma=$ lateral contraction per unit breadth/longitudinal extension per unit length. For a homogeneous isotropic substance-

$$
\begin{equation*}
n=\frac{\mathrm{E}}{2(1+\sigma)} \cdots(a) ; \quad \sigma=\frac{\mathrm{E}}{2 n}-1 \ldots(b) ; \quad k=\frac{\mathrm{E}}{3(\mathrm{I}-2 \sigma)} \tag{c}
\end{equation*}
$$

For an isotropic solid Poisson's Ratio must lie between $+\frac{1}{2}$ and -I , but for some materials it may, when deduced from E and $n$, exceed + r. (See Searle's "Elasticity.")

1 megabar $=10^{6}$ dynes per sq. $\mathrm{cm} .=987$ atmos $=1 / 1 \cdot 013$ atmos. $=$ the pressure measured by $750^{\circ} 15 \mathrm{mms}$. of mercury at $0^{\circ} \mathrm{C}$. sea-level, and latitude $45^{\circ}=749.66 \mathrm{mms}$, at $0^{\circ}$ in London.

The elasticities of a substance depend considerably upon its history. The extent of the agreement between the calculated and observed values of $n$ and of $\sigma$ below gives an indication of the degree of isotropy of the metals used. (Grüneisen, Reichsanstalt, Ann. d. Phy., 1908.)

## TENSILE STRENGTHS OF MATERIALS

Tenacities or breaking stresses in dynes per sq. cm . The elastic limit is always exceeded before the breaking stress is reached. The process of drawing into wire seems to strengthen the material, and the finer the wire the greater is the breaking stress. (See Poynting and Thomson's "Properties of Matter.")

For crushing and shearing strengths, see Ewing's "Strength of Materials" or one of the Engineering "Pocket-books." For bursting strengths of tubing, see p. 39; for tensile strengths of liquids, see p. 39 .

To reduce to kilogrammes per sq. mm., it is sufficient to divide by $10^{8}$; to lbs. per sq. inch, divide by $7 \times 10^{4}$; to tons per sq. inch, divide by $1.5 \times 10^{8}$. * Along the grain.

## COMPRESSIBILITIES OF ELEMENTS

Coefficient of compressibility $\mathrm{C}=\frac{1}{V} \cdot \frac{\delta \mathrm{~V}}{\delta p}$, where $\delta \mathrm{V}$ is the change in volume of a volume V under a change of pressure $\delta \rho$ (temp. constant).

The values of C below are per megabar (i.e. $10^{6}$ dynes per sq. cm.). To express as compressibility per atmosphere, increase C by $\frac{1}{80}$ of its value. Room temp. Pressure range, $100-500$ megabars. Based on compressibility of mercury $={ }^{\circ} 0_{0} 371$ per megabar. The results show a periodic relation with atomic weight. See also pp. 27, 28.
(Richards, Zeit. Phys. Chemr., 61, 1907, and Fourn. Chem. Soc., 191 I.)

## COMPRESSIBILITIES OF LIQUIDS

$C=$ compressibility per megabar (i.e. $10^{6}$ dynes per $\mathrm{cm} .{ }^{2}$ ). To express as com. pressibility per atmosphere, increase C by $\frac{1}{80}$ of its value.

As the pressure increases C becomes less. In general a rise in temperature increases the compressibility of a liquid; but water, however, shows a minimum value of C at about $50^{\circ} \mathrm{C}$. (Amagat). The compressibility of a solution diminishes as the concentration increases (see Poynting and Thomson's "Properties of Matter.").

Where the limits of pressure are not given, they are-for Amagat, 8--37 atmos. ; for Röntgen, 8 atmos. ; for Richards, $100-200$ atmos.

| Liquid. | Temp. | Comp. C per megabar. | Liquid. | Temp. | Comp. C per megabar. |

## VISCOSITIES OF́ LIQUIDS

If two parallel planes are at unit distance apart in a fluid, and one of them is moving in its own plane with unit velocity relatively to the other plane, then the tangential force exerted per unit area on each of the planes is equal to the viscosity. The dimensions of a viscosity are $\mathrm{ML}^{-1} \mathrm{~T}^{-1}$.

For the capillary-tube method of determining viscosities, Poiseuille's formula is, Viscosity $\eta=\frac{\pi \beta r^{4} t}{8 l \mathrm{~V}}$, where $p$ is the pressure difference between the two ends of the tube, $r$ the radius of the tube, $l$ its length, V the volume of liquid delivered in a time $t$.
viscosity of water
Determined by an efflux method and corrected for kinetic energy of outflow. (Hosking, Phil. Mag., 1909, 1, 502 ; 2, 260.)

## VISCOSITIES OF GASES AND VAPOURS

Clerk Maxwell showed in 1860 that, on the basis of the kinetic theory, the coefficient of viscosity of a gas would be independent of the pressure, and would vary as the square root of the absolute temperature. The first relation is true except at very low pressures ; the second deduction is not supported by experiment.

Of the formulæ connecting gaseous viscosity $(\eta)$ and temperature $(t)$, there are the convenient but only approximate relation of O. E. Meyer, $\eta_{t}=\eta_{0}(1+\alpha t)$, where $\alpha$ is a const. ; and the less manageable but accurate formula of Sutherland (Phil. Mag., 31, 1893), who, by taking account of the effects of molecular forces in bringing about collisions which otherwise would have been avoided, derived the expression $\eta_{t}=\eta_{0} \frac{273+\mathrm{C}}{\theta+\mathrm{C}} \cdot\left(\frac{\theta}{273}\right)^{\frac{3}{3}}$, where $\theta$ is the absolute temperature, and C is Sutherland's constant. The formula only holds for temps. above the critical, and for pressures such that Boyle's law is approximately obeyed. Sutherland's relation is thus of the form (which lends itself to graphical treatment), $\theta=\frac{K \theta^{3 / 2}}{\eta}-C$, where K is a constant. (See Fisher, Phys. Rev., 1907, 1909 et seq.; O. E. Meyer's "Kinetic Theory of Gases." For a bibliography of gaseous viscosity, see Pedersen, Phys. Rev., 25, 1907.) The values below are for dry gases.

## SIZE, VELOCITY, AND FREE PATH OF MOLECULES

$\rho=$ density of gas in gms./c.c. at $0^{\circ} \mathrm{C}$. $\mathrm{N}=$ number of molecules of gas per c.c. and 76 cms . at $0^{\circ} \mathrm{C}$. and 76 cms .
$p=1$ atmos. $=10132 \times 10^{6}$ dynes $/ \mathrm{cm} .^{2}$
$\theta=$ absolute temperature.
$\mathrm{R}=$ gas constant.
$\sigma=$ molecular diameter in cms.
$\begin{aligned} \mathrm{R} & =b \text { of Van der Waals' equation (p. 34). }\end{aligned}$
$k=$ thermal conductivity of gas (p. 52).
$c_{v}=$ specific heat at const. volume (p. 58).
$\eta=$ viscosity of gas (p. 31).
$m=$ mass of a single molecule (in grams).
$\mathrm{G}=$ square root of mean square molecular vel. (cm. $/ \mathrm{sec}$. at $0^{\circ} \mathrm{C}$.).
$\Omega=$ mean molecular velocity ( $\mathrm{cm} . / \mathrm{sec}$.).
$\mathrm{L}=$ length of mean free path in cms.

Assuming a Maxwell-Boltzmann distribution of velocities-

$$
\begin{aligned}
\mathrm{G} & =\sqrt{3 p /(\mathrm{N} m)}=\sqrt{3 p / \rho}=\sqrt{3 \mathrm{R} \theta} \\
\Omega & =4 \mathrm{G} / \sqrt{6 \pi}=92 \mathrm{I} \mathrm{G} \\
\mathrm{~L} & =\eta /(31 \rho \Omega)=2.02 \eta / \sqrt{p p} \\
\text { Collision frequency } & =\Omega / \mathrm{L}=5 \times 10^{\circ} \mathrm{per} \text { sec. for } \mathrm{O}_{2}
\end{aligned}
$$

## SIZE, VELOCITY, AND FREE PATH OF MOLECULES (conti.)

## MOLECULAR SIZE

The molecular diameter $\sigma$ has been calculated by the following formulx :1. The viscosity $\eta$ of a gas is a function of the size of its molecules.

$$
\eta=44 \rho \Omega /\left(\sqrt{2} \mathrm{~N} \pi \sigma^{2}\right) \text {. . Jeans } \therefore \sigma=\{0 \operatorname{og} 12 \rho \mathrm{G} /(\mathrm{N} \eta)\}^{\frac{1}{2}}
$$

2. The thermal conductivity, $k=1 \cdot 6 \eta c_{v}={ }^{1} 158 \rho \Omega c_{v} / N \sigma^{2}$

$$
\therefore \sigma=\left\{\cdot 14 \sigma_{\rho} \mathrm{G} c_{r} /(\mathrm{N} k)\right)^{\frac{1}{\alpha^{2}}}
$$

3. Van der Waals', $b=2 \pi \mathrm{~N} \sigma^{3} / 3 \quad \therefore \sigma=\{3 b /(2 \pi \mathrm{~N})\}^{\}^{3}}$
4. Limiting density, i.e. density D of densest known form. $\left.\sigma=\{6 \rho /(\pi \mathrm{DN})\}_{3}\right\}^{3}$

The values of $\rho$ and $\eta$ used in calculating $G$ and $L$ below are given on pp. 26,31. The values of $\sigma$ tabulated are mostly taken from Jeans' "Dynamical Theory of Gases," or Rudorf (Phil. Mag., 1909, p. 795). Jeans takes N $=4 \times 10^{10}$, while in the table following, the more recent value $2.75 \times 10^{19}$ has been used.

## CRIT!CAL DATA AND VAN DER WAALS' CONSTANTS

Critical temperature, $\theta_{c}$, is the highest temperature at which a gas can be liquefied by subjecting it to pressure.

Critical pressure, $p_{c}$, is the pressure (of gas and liquid) at the critical temperature.
Critical volume, $r^{\prime}$ c, is here defined as the ratio of the volume that a gas has at the critical temp. and press. to that which it wnuld have at $0^{\circ} \mathrm{C}$. and 760 mms ., i.e. it is the volume of gas at $\theta_{c}$ and $p_{c}$ which at N.T.P. would have unit volume. Some writers take the critical volume to be the specific volume (c.cs. per gram) at $\theta_{c}$ and $p_{c}$.

Most of the characteristic equations of state which have been proposed for gases take the form $\left(p+a / v^{2}\right)(v-b)=\mathrm{R} \theta$, where $p$ is the pressure, $v$ the volume, $\theta$ the absolute temperature of the gas, and R is the "gas constant." a expresses the mutual attraction of the molecules. The "covolume" $b$ is proportional to the space occupied by the molecules: O. E. Meyer takes $b=4 \sqrt{2}$ (volume of molecule). Van der Waals assumes $a$ is constant: if this were true the constant volume and thermodynamic scales of temperatures would agree - they do not, however (see p. 44). Joule and Thomson, Clausius, Amagat, and Berthelot, among others, regard $a$ as a function of $\theta(e . g . a \propto \mathbf{I} / \theta)$, and $b$ as constant.

Assuming with Vian der Waals that $a$ and $b$ are constants, the equation can be regarded as a cubic in $v$, which has its three roots equal at the critical point, whence $a=27 \mathrm{R}^{2} \theta_{c}{ }^{2} /\left(64 p_{c}\right)$, and $\dot{b}=\mathrm{R} \theta_{c} /\left(8 p_{c}\right)$.

Taking pressures in atmos., and the volume of the gas at $\circ^{\circ} \mathrm{C}$. and I atmos. as $\mathrm{I}, \mathrm{R}=p v / \theta=\mathrm{I} / 273$. In these units, $b$ is in terms of the volume of the gas at $0^{\circ} \mathrm{C}$. and 1 atmos.

Example.-For $\mathrm{CO}_{2} p_{c}=73$ atmos. and $\theta_{c}=273+31^{\circ 1}=304 \cdot 1$, whence $b=30+1 /(8 \times 273 \times 73)={ }^{\circ}$ oorg! of the volume of the gas at $0^{\circ} \mathrm{C}$. and I atmos.

See Preston's "Heat," Nernst's "Theoretical Chemistry," Young's "Stoichiometry," Berthelot (Tirav. et Mém. Bur. Intl., 1907). * Indicates calculated values.

## DIFFUSION OF GASES

The Ccefficient of diffusion, D, is the mass of the "diffusing" gas which crosses unit area in unit time under unit concentration gradient : the dimensions of the coefficient are $\mathrm{cm} .^{2} \mathrm{sec} .^{-1}$. D is inversely proportional to the total pressure of the two gases, and roughly proportional to the square of their absolute temperature. Total pressure 1 atmosphere. $\mathrm{H}_{2}-\mathrm{O}_{2}$ implies that $\mathrm{H}_{2}$ is diffusing into $\mathrm{O}_{2}$.
(Sce Meyer's "Kinetic Thcory of Gases.")

## DETERMINATION OF ALTITUDES BY THE BAROMETER

Babinet's formula (Compt. Rend., 1850 ) is, Altitude $=\frac{\mathrm{C}\left(\mathrm{H}_{1}-\mathrm{H}_{2}\right)}{\mathrm{H}_{1}+\mathrm{H}_{2}}$, where $\mathrm{H}_{1}=$ barometer reading at lower station, $\mathrm{H}_{2}$ at upper station. If altitudes are in metres, and barometric heights in mms.,

$$
\mathrm{C}=32\left(500+t_{1}+t_{2}\right)
$$

where $t_{1}$ and $t_{2}$ are the corresponding station temperatures ( ${ }^{\circ} \mathrm{C}$.).
In the table below the mean temperature, $\left(t_{1}+t_{2}\right) / 2$, is taken as $10^{\circ} \mathrm{C}$., and the barometric height at sea-ltvel as 760 mm ., so that alitudes are in metres above sea-level. The values are of course only approximate. Babinet's formula is not applicable to very great altitudes.

| Altitude | 0 | 100 | 200 | 300 | 400 | 500 | 600 | 700 | 800 | 900 |

## SURFACE TENSIONS

In dynes per cm . (A) indicates liquid in contact with air, (V) indicates liquid in contact with its vapour. The surface tension of a liquid varies somewhat with the age (and contamination) of the surface.

Temperature variation. It follows from Eötvos' rule, that the surface tension T at temp. $t$ is approximately proportional to ( $t_{c}-t$ ), where $t_{c}$ is the critical temp., the constant of proportionality being much the same for chemically similar substances. The surface tension at $t_{\mathrm{c}}$ is zero. (For critical temps. see p. 34.)

See Poynting and Thomson's "Properties of Matter."
WATER ( $\iota_{c}=365^{\circ} \mathrm{C}$.)

## RELATIVE HUMIDITY AND DEW-POINT

Relative humidity $=\frac{[p]_{e}}{[p]_{t}^{]}}$. Ico, where $[p]_{c}$ is the actual pressure of water-vapour at temperature $t^{\circ}$, and is e pual to $[\phi]_{l, t,}^{p}$, the saturated vapour pressure at the dewpoint $\left.(d p) ;[p]_{\varepsilon}\right]^{\text {is }}$ the pressure of saturated vapour at $t^{\circ}$. For a table of saturated water-vapour pressures, see p. 40. (See "Smithsonian Meteorological Tables.")

Percentage relative humidities for different dew-points and dew-point depressions are tabulated below.

## WET AND DRY BULB HYGROMETER

Apjohn (1835), August ( 1825 ), and others, by making various assumptions (some of doubtful legitimacy), have derived formule of the type-

$$
[p]_{w}^{w_{w}}-[p]_{t}=\mathrm{AH}\left(t-t_{v}\right)\left[\mathrm{I}+\mathrm{B}\left(t-t_{w}\right)\right]
$$

where $t$ is the temperature of the dry bulb, $t_{10}$ that of the wet, $[p]$, is the actual pressure of water-vapour in the air (at temperature $t),[p]_{w}^{3}$ is the saturated vapour pressure of water at the temperature $\left(t_{w o}\right)$ of the wer bulb, H is the baronetric height, and A and B are constants. (See Love \& Smeal, 1911.)

The indicat ons of this hygrometer are so dependent on its environment that for most purposes B may be taken as zero, and H as constant, say 760 mmis.

If H is measured in millimetres, and temperatures in Centigrade degrees, the following values of A are suitable for the conditions mentioned :-
$\mathrm{A}=.00068$ for moving air, as in a ventilated hygrometer.
$\mathrm{A}={ }^{0} 0075$ in a Stevenson screen as used by Meteorological Office.
$\mathrm{A}=.0008$ in open air with slight wind.
$A=\cdot 00084$ in open air with no wind.
$\mathrm{A}={ }^{\circ} \mathrm{oor}$ in a small closed room.
Rizzo (1897) takes $\mathrm{A}=00075$ and $\mathrm{B}=-\cdot 003$, and the table below is derived by employing these values. [ $p]_{w_{w}}^{\text {c }}$ can be got from the table of saturated vapour pressures on p .40 , and thus the desired vapour pressure $[p]_{\mathrm{c}}$ can be determined.

$$
\text { Values of }[p]_{w}^{3}-[p]_{c} \text { (Rizzo) }
$$

## WET AND DRY BULB HYGROMETER (contd.) GLAISHER'S FACTORS

Mr. Glaisher, in $1841-5$, took many thousands of observations with the wet and dry bulb hygrometer in Greenwich, India, and Toronto, and from simultaneous readings of a Daniell's hygrometer (now recognized as being an untrustworthy instrument) drew up a table of "factors."

The factor $(f)$ at any dry-bulb reading is defined by

$$
\text { depression of dew-point }=t-t_{d p}=f\left(t-t_{w}\right)
$$

the notation being as above. Glaisher's factors are employed by the Meteorological Office and the Meteorological stations in this country. The hygrometer readings are taken in a Stevenson screen, which is essentially a box with double louvred sides.

The factors for a range of dry-bulb temperatures are tabulated below. The formula above yields the dew-point; and the saturated vapour pressure at the dewpoint gives the actual vapour pressure at $t^{\circ}$. For a table of saturated vapour pressures, see p. 40. (See "The Observers' Handbook," Meteorological Office.)

| Dry Bulb <br> Temp. $(t)$. | $\mathbf{0}$ | $\mathbf{1}$ | $\mathbf{2}$ | $\mathbf{3}$ | $\mathbf{4}$ | $\mathbf{5}$ | $\mathbf{6}$ | $\mathbf{7}$ | $\mathbf{8}$ | $\mathbf{9}$ |

## TENSILE STRENGTHS OF LIQUIDS

Liquids perfectly free from air can sustain considerable tension without rupture, e.g. water can withstand a tension of 5 atmospheres, alcohol 12, and strong sulphuric acid 12 atmospheres. Extensions of volume of $0.8 \%$ for water, $I^{\cdot 1} \%$ for alcohol, and $1.7 \%$ for ether have been obtained. The volume elasticity (p.29) of alcohol is the same for extension as for compression. (See Worthington, Phil. Trans. A., 1892 ; Dixon, Proc. lioy. Dub. Soc., 1909 ; Berthelot, Ann. Chimin. Phys., 30, 1850; Poynting and Thomson's "Properties of Matter.")

## BURSTING STRENGTHS OF GLASS TUBING

Bursting pressures in atmospheres for German soda glass tubing. Most glasstubing is in a state of considerable strain, and a factor of safety of not less than two should usually be employed. (Roebuck, Phys. Rev., 1909; and Onnes and Braak, Kon. Ak. Wet., Amsterdam, 1908.) Ordinary boiler water-gauge glasses stand between 12 and 24 atmospheres.

| Thickness of Wall. | Bore. |  |  |  |  |  |  |

## VAPOUR PRESSURES

Inter and Extrapolation of Vapour Pressures.-The Kirchhoff-RankineDupre formula, $\log p=\mathrm{A}+\mathrm{B} / \theta+\mathrm{C} \log \theta$, where $p$ is the vapour pressure, $\theta$ the absolute temperature, and A, B, C are constants, is accurate and convenient (e.g. see p. 41). For values of A, B, C, see Juliusburger, Ann. d. Phys., p. 618, 1900.

Ramsay and Young's Method. - If two liquids, one at absolute temperature $\theta$ and the other at $\theta^{\prime}$, have the same vapour pressure, the ratio $\theta / \theta^{\prime}$, when plotted against $\theta$, gives a straight line. This method may be used to find roughly the vap. press. of a substance at any temperature when only its boiling-point is known.

Interpolation by Logarithms. - The curve of vapour pressure ( $p$ ) against temp. ( $t$ ) is approximately hyperbolic, and thus $\log p$ plotted against $t$ gives a graph of slight curvature, which over $10^{\circ}$ intervals of $t$ may, for approximate work, be regarded as a straight line: thus the following method of interpolation :-

Example.-Required vap. press. of water at $15^{\circ}$, given

$$
\begin{array}{cccc}
t & p & \log p \\
10^{\circ} & 9^{\circ} 2 & 964 & .96++1 \cdot 243 \\
20^{\circ} & 17^{\circ} \cdot 5 & 1^{2} 243 & \frac{1}{2}=1 \cdot 104=\log 12 \cdot 7 ; \text { i.e. } p \text { at } 15^{\circ}=12 \cdot 7, \\
& \text { actually it is } 12 \cdot 8 .
\end{array}
$$

## VAPOUR PRESSURE OF ICE

In mms. of mercury at $0^{\circ} \mathrm{C} . ; g=980.62 \mathrm{cms}$. per sec. ${ }^{2}$; hydrogen (const. vol.) scale of temps. (Scheel, and Heuse, Reichsanstalt Ann. d. Phys., 1909.)

| Temp. . | $-50^{\circ} \mathrm{C}$ | $-40^{\circ}$ | $-30^{\circ}$ | $-20^{\circ}$ | $-10^{\circ}$ | $-5^{\circ}$ | $-2^{\circ}$ | $0^{\circ}$ |

Interpolate logs of vapour pressures as explained on p. 40.

## VAPOUR PRESSURES OF ELEMENTS

$p=$ vapour pressure in mms. of mercury at $0^{\circ}$ C. lat. $45^{\circ}$ and sea-level $(g=98062)$ (i.e. $1 \mathrm{~mm} . \mathrm{Hg}=1333^{\circ} 2$ dynes per $\left.\mathrm{sq} . \mathrm{cm}\right)$. If followed by at., $p$ is in atmospheres; $\theta=$ absolute temp. (A.) ; $t=$ temp. in ${ }^{\circ} \mathrm{C}$. ; ( $s$ ) solid; ( $l$ ) liquid. The thermometry is in many cases somewhat dubious.

[^5]
## GAS THERMOMETRY

The standard thermometric scale of the International Committee of Weights and Measures (1887) is that of the constant-volume hydrogen thermometer, the hydrogen being taken at an initial pressure at $0^{\circ}$ C. of 1000 mms , of mercury measured at $0^{\circ} \mathrm{C}$. sea-level and lat. $45^{\circ}(=1.3158$ standard atmosphere).

THERMODYNAMIC TEMPERATURE OF THE ICE-POINT

| Method. | $\mathrm{H}_{2}$ | $\mathrm{N}_{2}$ | Air. | $\mathrm{CO}_{2}$ | Computer. |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | ${ }^{\circ}$ | ${ }^{\circ}$ |  | $\bigcirc$ |  |
| From Joule-Thomson effect | 273.14 | $273^{\circ} 09$ | - | $273 * 05$ | Callendar, 1903 |
| Extrapolation to zero pressure <br> (see p. 54) | $273 \cdot 07$ | $273^{\circ} 09$ | - |  | Berthelot and Chappuis, 1907 |
| From Joule-Thomson effect | 273.05 | (273.17) | 273*19 | 273.10 | Berthelot, 1907 |
| " | 273.06 | 273.25 | $273{ }^{\circ} 27$ | $273 \cdot 12$ | Buckingham,1908 |
| " " | $273^{\circ} 13$ | 273.14 |  | - | Rose-Innes, 1908 |

General mean $=273^{\circ} \cdot 13$.

## THERMODYNAMIC CORRECTIONS TO GAS SCALES OF TEMPERATURE

The corrections to both the constant-pressure (C.P.) and the constant-volume (C.V.) scales are either ( 1 ) derived from characteristic equations of state (Callendar, 1903; Berthelot, 1907), or (2) in the case of the C.P. thermometer, computed from the Joule-Thomson effect ; whence from these C.P. corrections and a knowledge of the compressibility of the gas under different conditions the C.V. corrections can be calculated. Chappuis (1907)* has experimentally compared the C.P. and C.V. H . and N. thermometers each with mercury thermometers. The values below are based on computations by Callendar (Phil. Mag., 1903), Berthelot* (from Chappuis' data 1907), Onnes and Braak (1907 and 1908), Rose-Innes (Phil. Mag., 1908), and Buckingham (1908).t There is some divergence among the different computations for hydrogen; the agreement is much better in the case of nitrogen. The thermodynamic correction to the C.V.H. thermometer is negligible, and with nitrogen also at extreme temps. the correction is less than the error of working in modern gas thermometry. The values for air are a little smaller than for nitrogen ; for helium they are slightly larger than for hydrogen except at the lowest temperatures, when the helium corrections are the smaller. New experiments on the JouleThomson effect are needed. $\ddagger(+)$ means that the correction has to be added to the gas scale temperature to give the thermodynamic temperature. The correction is proportional to the initial pressure of the gas in the thermometer.

## MERCURY THERMOMETRY

## CORRECTIONS TO REDUCE MERCURY-IN-GLASS SCALE TEMPS. TO GAS SCALE TEMPS.

The values for the English Kew glass (which is a lead potash silicate) are due to Harker (1906) ; the verre dur corrections are given by the International Bureau; those for the Jena glasses by Grützmacher. The method at Kew is to determine the ice-point correction before an observation is made. The other glasses have their ice-point or zero depressions determined immediately after each temperature reading. See Guillaume's "Thermométrie de Précision." Paris, 1889, and Chree's "Notes on Thermometry," Phil. Mag., 1898. The French glass, verre dur, is used by Tonnelot of Paris. The normal glass, Jena $16^{\prime \prime \prime \prime}$, may be known by the presence of a thin violet line near the surface. Jena $59^{\prime \prime \prime}$ is a borosilicate (p. 74).

DEPRESSION OF ZERO OF MERJURY THERMOMETERS
The values indicate the zero depressions after the thermometer has been heated to the temp. stated. They have been determined by Guillaume, Thiesen, Schloesser, and Böttcher because of the impossibility in practice of interrupting a series of temperature measurements to take a number of zero readings (see above).

STEM-EXPOSURE OR EMERGENT-COLUMN CORRECTION
The table below gives the (additive) "stem-exposure" correction for ( I ) the ordinary solid-stem thermometer, and (2) the German pattern sleeve-thermometer, which has a fine capillary in an outer glass tube. Both thermometers are of Jena $16^{\prime \prime \prime}$ glass, with degree intervals about I mm. long.
$t$ is the indicated temperature, and taux the temperature of an auxiliary thermometer whose bulb is 10 cms . from and on a level with the mid-point of the eyposed stem. The auxiliary thermometer must be shielded from the source of heat. (See Watson's "Practical Physics," and Rimbach, Zeit. f. Inst., 10, 1890.)

## 46 <br> ELECTRICAL THERMOMETRY

## PLATINUM THERMOMETRY

TO REDUCE PT-SCALE TEMPS. ( $\left.t_{p}\right)$ TO CONST. VOL. N-SCALE TEMPS. ( $t$ )
Callendar's "difference formula" for the difference between the nitrogen-scale temp. ( $t$ ) and the Pt-scale temp. ( $t_{p t}$ ) is $t-t_{p t}=\delta \cdot t(t-100) \mathrm{IO}^{-1}$, where $\delta$ is close to 15. Pt-scale temps. result from assuming a linear relation $\mathrm{R}_{p t}=\mathrm{R}_{\mathrm{0}}\left(\mathrm{I}+a t_{p t}\right)$ between temp. and the electrical resistance (R) of $\mathrm{Pt} ; \alpha$ is the mean coefficient for the range $0^{\circ}$ to $100^{\circ}$. The "difference formula" gives the correction yielded by the truer parabolic relation $\mathrm{R}_{t}=\mathrm{R}_{0}\left(1+\alpha t+\beta t^{2}\right)$. Pt thermometers should not be used above $1200^{\circ}$ C. (See Callendar, Phil. Mag., 1899, 1, p. 191; 2, p. 519. Camb. Sci. Inst. Co.'s list "Technical Thermometry;" and (for bibliography), Waidner and Burgess, Bull. Bur. of Standards, 1909.)

$$
\delta=1 \cdot 50

## HIGH TEMPERATURES

(See Burgess and Le Chateliers "High Temperature Measurements, 1912.")
For the neasurement of high temperatures (say above $1200^{\circ} \mathrm{C}$., which is about the present upper experimental limit of the gas scale) the instruments in general use are thermo-junctions and optical or radiation pyrometers. Both involve extrapolation. Thermo-couples have been used up to the temperature of the meltingpoint of platinum $\left(c .1750^{\circ}\right)$. At high temperatures thermo-junctions yield rather lower results than do optical pyrometers, c.g. see the M.P.'s of P.d and P' on p. 49.

## THERMO-ELECTRIC THERMOMETRY

Temperature readings with thermo-couples are redaçed by one of the formula: : $(a) \mathrm{E}=a+b t+c t^{2}$, (b) $\mathrm{E}=m t^{n}$, or $\log \mathrm{E}=n \log t+m^{\prime}, \mathrm{E}$ Leing the e.m.f. generated, and $t$ the temperature of the hot junction, the cold junction being at $0^{\circ}$. Up to about $1200^{\circ}$ these formulæ with suitable constants agree to within $2^{\circ}$ for the usual $10 \%(\mathrm{Pt}, \mathrm{Pt}-\mathrm{Rh})$ and ( $\mathrm{Pt}, \mathrm{Pt}-\mathrm{Ir}$ ) couples, but above $1200^{\circ}$ formula (b) yields the higher results, e.g. see the melting-points of Pd and Pt on p. 49. The thermo-e.m.f.'s of these Pt couples gradually diminish with prolonged heating. The values of the constants below are only average values,

$\ddagger 84 \mathrm{Cu}, 4 \mathrm{Ni}, 12 \mathrm{Mn}$.

## RADIATION AND OPTICAL THERMOMETRY

Most radiation thermometers depend upon either ( 1 ) the Stefan-Boltzmann law, $\mathrm{E}=\mathrm{K}\left(\theta^{4}-\theta_{0}{ }^{4}\right)$, where E is the total energy (all wave-lengths) radiated per sec. by a black body at absolute temp. $\theta$ to surroundings at absoite temp. $\theta_{0}$, and K is a const. ( $K=5.7 \times 10^{-12}$ watts per $\mathrm{cm} . .^{2}$ per $1^{\circ}-\sec \mathrm{p}, 65$ ) ; or (2) Wien's equation connecting the temperature with the intensity of scme particular wave-length of light
emitted (p. 65 ). The Wien equation is, Intensity $I=c_{1} \lambda-{ }^{-5} e^{-\frac{c_{2}}{\lambda T}}$, where $\lambda$ is the wave-length, $T$ is the "black body" temp. on the absolute scale, $c_{1}$ and $c_{2}$ are constants, and $e$ is the base of the Napierian logarithms. Both equations give results which agree very accurately with the gas scale over the calibrated range $0^{\circ}$ to $1200^{\circ} \mathrm{C}$. Up to about $1500^{\circ}$ radiation thermometers are, in practice, almost always graduated empirically, usually against a thermo-couple.

The "black body" temperature of a radiating substance is the temperature at which an ideal black body would emit radiation of the same intensity as that from the substance, the radiation considered being of some particular wave-length. A perfectly black body absorbs all the radiation which falls upon it; it is destitute of reflecting power. Coal, carbon, metals which when heated tarnish with a black oxide, enclosed furnaces and muffles at a uniform temperature, all conform very nearly to this definition. When a pyrometer is sighted upon a body which is not "black," the temperature recorded-the "black body" temperature-will be lower than the true temperature to an extent which increases with the refl.cting power of the body, c.g. if platinum and carbon have equal "black body" temperatures, their actual temperatures may differ by $180^{\circ}$ or so at $1500^{\circ}$.

## STANDARD TEMPERATURES

Melting and boiling points of elements will be found on p. 48 ; of chemical compounds, on p. 10).
B.P. $=$ boiling point at $760 \mathrm{~mm} . ;$ M.P. $=$ melting point $;$ T.P. $=$ transition point.

| Substanie. |  | Temp. | Substance. |  | Temp. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Hydrogen | B.P. | 0 -253 -2. | Zinc* |  | ${ }^{\circ} \mathrm{C}$. 419.4 |
| Oxygen | 13.P. | -183 | Sulphur* | B. P. | $4+1 \times 7$ |
| Carbon dioxide | B. P. | - 78.2 | Aluminium | M.P. | 657 |
| Mercury | M.P. | - 38.8 | NaCl (Harker). | M.P. | 801 |
| Water | M. P. | - | $\mathrm{K}_{2} \mathrm{SO}_{4}$. . . | M.P. | 1070 |

$\ddagger$ Positive crater.

## EFFECT OF PRESSURE ON BOILING POINTS

$\delta \phi / \delta t$ is given as mm . Hg per degree C. for pressures not very far removed from 760 mm .

The boiling point in absolute degrees $C$. of a substance under $760 \mathrm{~mm} .=t$ $+c(760-p)(t+273)$, where $c$ is a constant for the substance, and $t$ is the B.P. in degrees $C$. at the pressure $p \mathrm{~mm}$. The constant $c$ is the same for chemically similar substances.
(See Young, "Fractional Distillation.")

| Substanoe. | $\delta p / \delta t_{1}$ | $c$ | Substance. | $\delta p / \delta t$ | c | Substance. | $\delta p / \delta t$ | ${ }^{\circ}$ |

## THERMAL CONDUCTIVITIES

The thermal conductivity, $k$, is given below as the number of (gram) calories conducted per sq. cm . per sec. across a slab of the substance 1 cm . thick, having a temp.-gradient of $I^{\circ} \mathrm{C}$. per cm ., i.e. calorie $\mathrm{cm} .^{-1}$ sec. ${ }^{-1}$ temp. ${ }^{-1}$. (See Callendar, "Conduction of Heat," Eincyc. Brit., and Winkelmann's "Handbuch der Physik.," III., 1906.)

## METALS AND ALLOYS

$k$ for most pure metals decreases with rise of temperature ; the reverse appears to be true for alloys. If $\boldsymbol{\varepsilon}$ be the electrical conductivity and $\theta$ the absolute temp., then $k /(\kappa \theta)$ is very approximately a constant for pure metals. (See J. J. Thomson, "Corpuscular Theory of Matter," and Lees, Phil. Trans., 1908.) The electrical conductivity of the same specimen of many of the substances below will be found on p . 8 I .

| Substance. | Temp. | Cond.k. | Observer. | Substance. | Temp. | Cond.k. | Observer. |

## GASES

In the case of a gas the thermal conductivity $k=1 \cdot 603 \eta c_{v}$, where $\eta$ is the viscosity, and $c_{v}$ the specific heat at constant volume. Stefan, and Kundt and Warburg have found, in agreement with this formula, that $k$ for air, hydrogen, etc., is constant between the pressures 76 cm . and 1 cm . $k$ increases with the temperature. (See Meyer's "Kinctic Theory of Gases.")

## COEFFICIENTS OF. LINEAR EXPANSION OF SOLIDS

To represent accurately over any considerable range the variation of length $(l)$ with temperature $(t)$ requires for almost-all solid substances a parabolic or cubic equation in $t$. But if the temperature interval is not large, a linear equation $l_{t}=l_{0}(\mathrm{I}+\alpha t)$ may be employed; and this gives a definition of the mean coefficient of linear expansion (a) over that temperature range. The coefficient of cubical expansion $=3 a$ :

There is little point in tabulating coefficients of higher-powered terms of $t$, since for a given specimen it is as a rule impossible without measurement to assume with any accuracy anything more definite than the average value of even the first power coefficient (a): Except in a few cases the linear coefficient as defined above increases with the temperature. The values of $\alpha$ subjoined are per degree. C , and except when some temperature is specified, for a range round and about $20^{\circ} \mathrm{C}$. Some substances expand irregularly, and extrapolation of a may therefore be dangerous. Interpolation of $\alpha$ from the constituent metals must be employed with caution in the case of alloys. (See Winkelmann's "Handbuch der Physik," "iii. 1906.)

## COEFFICIENTS OF CUBICAL EXPANSION OF GASES

The volume coefficient, $\alpha$, at constant pressure is defined by $v_{t}=v_{0}(1+a t)$; the pressure coefficient, $\beta$, at constant volume is defined by $p_{t}=p_{0}(1+\beta t)$, where $v_{t}$ and $p_{t}$ are the volume and pressure respectively corresponding to $t^{\circ}$, the initial volume and pressure $\left(v_{0}, t_{0}\right)$ being measured at $o^{\circ} \mathrm{C}$. The values of both $\alpha$ and $\beta$ depend on the initial pressure of the gas. If a gas obeys Boyle's law exactly, $\alpha=\beta$.

Comparison of rarefied gas, $\mathbf{H}_{2}$ and absolute temperature scales.By graphically or otherwise extrapolating $\alpha$ and $\beta$ to zero pressure, they become equal (as we should expect, for rarefied gases should behave as ideal gases and obey Boyle's law), and we may write $\alpha=\beta=\gamma$. For example, Berthelot finds from Chappuis' data-

$$
\begin{aligned}
\text { For } \mathrm{H}_{2}, \text { mean } \gamma & =00366207=1 / 273^{\circ} \circ 7 \text { (see p. 44) } \\
\mathrm{N}_{2}, \quad \eta \gamma & =00366182=1 / 273^{\circ} \circ 9 \text { (see p. 44) }
\end{aligned}
$$

Kelvin's absolute temperature scale agrees with the ideal gas scale, and therefore with the rarefied gas scale. Now, as will be seen below, $\beta$ for $\mathrm{H}_{2}=\gamma$ very nearly, and thus the constant-volume hydrogen scale of temperature may justifiably be taken as closely approximating to the thermodynamic scale (see also p. 44).
(See Young's "Stoichiometry"; and Berthelot and Chappuis, Trav. et Mém. du Bur. Intl., 1907.)

## 55 <br> COEFFICIENTS OF EXPANSION

## COEFFICIENTS OF CUBICAL EXPANSION OF LIQUIDS

As with solids (see p. 52), if the temperature interval is not large, a linear equation $\tau_{t}=v_{0}(\mathrm{I}+a t)$ may be employed to show the relation between the volume $(v)$ of a liquid and its temperature ( $t$ ). The mean cocfficient $(a)$ thus defined increases in general with the temperature. The values of $\alpha$ subjoined are per ${ }^{\circ} \mathrm{C}$., and for a range round $18^{\circ} \mathrm{C}$. unless otherwise specified.

## MECHANICAL EQUIVALENT OF HEAT

Joule's equivalent, J, is here given as the number of ergs equivalent to a calorie, i.e. the heat required to raise 1 gram of water through $1^{\circ} \mathrm{C}$. at some specified temperature. The $15^{\circ}$ calorie is about I part in Icoo greater than the $20^{\circ}$ calorie. (See p. 56.)

See Griffith's "Thermal Measurement of Energy," 1901.

| Observer. | Calorie. | Ergs. |  | Observer. | Calorie. | Ergs. |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- |
|  |  | N. scale | $\times 10^{\circ}$ |  |  |  |

## SPECIFIC HEAT OF WATER

Callendar and Barnes (Phil. Trans., 1902) used an electrical method of determining the temperature variation of the specific heat of water. The specific heats below are reduced by Callendar ("Ency. Brit." Art. "Calorimetry") from their results; they are relative to the specific heat at $20^{\circ} \mathrm{C}$. on the C.P. nitrogen scale. The $20^{\circ}$ calorie (see pp. 5 and 55 ) is adopted as $4^{\circ} 180$ joules $=4.180 \times 10^{7}$ ergs, being the mean of the results of Rowland (1879) and of Reynolds and Moorby (reduced), each of whom used a mechanical method of determining "J." Thus the values of J below do not rest on the values attributed to the electrical standards employed. The specific heat of water is a minimum at $37.5^{\circ} \mathrm{C}$., according to Callendar and Barnes.

The $15^{\circ}$ calorie (according to Barnes, Proc. Roy. Soc., 1909 ) $=4^{\circ} 184$ joules, assuming the e.m.f. of the Clark cell at $15^{\circ} \mathrm{C}$. $=14330$ international volts.

The mean calorie ( $={ }_{100}^{100}$ of heat required to raise 1 gram of water from $0^{\circ}$ to $100^{\circ} \mathrm{C}$.) $=4 \cdot 185$ joules (Barnes, 1909) $;:=4 \cdot 184$ joules (Reynolds and Moorby, 1897 , corrected by Smith).

## SPECIFIC HEAT OF MERCURY

In terms of the gram calorie at $15^{\circ} .5$ on the const. vol. H. scale. (Barnes and Cooke, Phys. Rev., 15, 1902.) Mercury has a minimum specific heat at $140^{\circ} \mathrm{C}$. (Barnes, Brit. Ass. Rep., 1909. )

| Temp. | $0^{\circ} \mathrm{C}$ | $20^{\circ}$ | $40^{\circ}$ | $60^{\circ}$ | $80^{\circ}$ | $100^{\circ}$ | $200^{\circ}$ |

## RATIO OF THE SPECIFIC HEATS FOR GASES AND VAPOURS

$\gamma=$ the ratio of the specific heat at constant pressure to that at constant volume. $\gamma$ is usually determined directly by some method involving an adiabatic expansion, such as the determination of the velocity of sound in the gas. From a knowledge of either (1) the pressure or (2) the temperature immediately following an adiabatic expansion (Clément and Desormes, Lummer and Pringsheim's methods respectively), $\gamma$ can be deduced from $p v^{\gamma}=$ const., or $\theta v^{\gamma-1}=$ const.
(See Capstick, "Science Progress," 1895 ; and Moody, Phys. Rev., Ap., 1912.)

## LATENT HEAT OF VAPORISATION

Latent heats are given as the number of gram calories required to convert I gram of substance from liquid into vapour without change of temperature. The latent heat of vaporisation vanishes at the critical temperature.

Trouton's Rule.-The latent heat of vaporisation of i gramme molecule of a liquid divided by the corresponding boiling point (on the absolute scale) is a constant ( C ). $\mathrm{C}=21$ for substances of which both liquid and vapour are unassociated. If the liquid is associated, $C>21$ (e.g. water, $C=26$ ); if the vapour is associated, $C<2$ (e.g. acetic acid, $C=15)$.
[See Nernst's "Theoretical Chemistry."]

## STEAM

Regnault's equation connecting latent heat and temperature takes no account of the temperature variation of the specific heat of water (see p. 56). The equation gives values which are too large at low temperatures. The equations of Griffiths, Henning, and Smith háve been reduced and are here expressed in terms of the $15^{\circ}$ calorie $=4^{\circ} 184$ joules. Griffiths' and Smith's results rest further on an attributed value of 1433 volts for the e.m.f. of the Clark cell at $15^{\circ} \mathrm{C}$.

See also next page.
[The critical temp. of water is about $365^{\circ} \mathrm{C}$.]

| Observer. | Temp. range of expts. | Latent heat $\mathbf{L}_{t}$ at $t^{\circ} \mathbf{C}$. |
| :---: | :---: | :---: |

## THERMOCHEMISTRY

In thermoshemistry the conservation of energy is assumed in accordance with experiment, and consequently ( I ) if a cycle of chemical change takes place so that the final state of the reacting substances is identical with the initial, then as much heat is absorbed as is given out, i.e. the total heat of the reaction is zero; (2) the heat of reaction only depends on the initial and final states of the reacting substances, and not on the intermediate stages. The results below are affected by, but have not been corrected for, any changes in the accepted values of the atomic weights since the experiments were carried out.

## MOLECULAR HEAT OF FORMATION

The molecular heat of fomation (H.F.) is the heat liberated when the molecular weight in grams of a compound is formed from its elements. When the state of aggregation of an element or compound is not given, it is the state in which it occurs at room temperature and pressure. A minus sign before an H.F. means that heat is absorbed in the building up of the compound.

Unit-the gram calorie (at $15^{\circ}$ to $20^{\circ} \mathrm{C}$.) per gm. molecule of compound. Aq $=$ solution in a large amount of water. The reactions are at constant pressure.

Example.-H.F. of $\mathrm{CuSO}_{4}=183,000$; of $\mathrm{CuSO}_{4} \cdot \mathrm{Aq}=198,800 . \therefore$ the heat of solution of $\mathrm{CuSO}_{4}=198,800-183,000=15,800$ cals. per gram mol.
(T., Thomsen, "Thermochemistry," trans. by Miss K. A. Burke ; B., Berthelot, Ann. d. Chim. et d. Phys., i878; T.B., mean of both these observers' values. For organic compounds, see p. 64 .

## MOLECULAR HEAT OF NEUTRALISATION

Unit-the gram calorie (at $15^{\circ}$ to $20^{\circ}$ ) per gram molecule of base. Thus $\mathrm{KOH} \cdot \mathrm{Aq}+\mathrm{HCl} \cdot \mathrm{Aq}=\mathrm{KCl} \cdot \mathrm{Aq}+\mathrm{H}_{2} \mathrm{O}+13,750$ calories. Thomsen ( $=\mathrm{T}$.) observed at $18^{\circ}$ to $20^{\circ} \mathrm{C}$., and the final dilution was 3600 gms . ( 7200 for Na salts) per gm . mol. of base. Berthelot ( $=$ B.) used at least 2000 gms . of $\mathrm{H}_{2} \mathrm{O}$ per 17 gms . of hydroxylion, - HO.

HEATS OF COMBUSTION AND FORMATION OF CARBON COMPOUNDS, COAL, ETC.
Molecular heats of formation (H.F.) of organic compounds are deduced from their heats of combustion (H.C.), by subtracting the Jatter from the heat generated on burning the carbon and hydrogen contained in the compound. Experimental errors in the H.C. thus become magnified in the H.F. Heats of combustion determined by Thomsen are for the vapour of the compound at $18^{\circ} \mathrm{C}$.; for the liquid the H.C. and H.F. would be greater by the latent heat of evaporation. Thomsen assumes H.F. of $\mathrm{CO}_{2}$ from amorphous C as $=96,960$ cal.; of water as 68.360 cal. per gm. molecule. For H.F. of inorganic compounds, see p. 62.

The H.C. and H.F. of carbon compounds is an additive property (see Thomsen's "Thermochemistry"). Berthelot's bomb calorimeter has been of considerable importance in the modern experimental side of the subject.

Unit-the gram calorie (at $15^{\circ}$ to $20^{\circ}$ ) per gram molecule.
Example. 16 gms . of methane, $\mathrm{CH}_{4}$, give out 212,000 gram calories of heat when burnt at constant pressure, to water and $\mathrm{CO}_{2}$ at $18^{\circ} \mathrm{C}$.
(T., Thomsen, "Thernochemistry;" B., Berthelot.)

## MOLECULAR HEAT OF DILUTION

The heat set free or absorbed on diluting a gram molecule of liquid with water is the molecular heat of dilution: thus on diluting HCl to $\left(\mathrm{HCl}, 300 \mathrm{H}_{2} \mathrm{O}\right), 17,300$ calories per $36^{\circ} 5$ grams of HCl are set free ; diluting $2 \mathrm{NaCl}, n \mathrm{H}_{2} \mathrm{O}(n=20)$ to ( $2 \mathrm{NaCl}, 100 \mathrm{H}_{2} \mathrm{O}$ ) absorbs 1060 cal. per $2 \times 58.65 \mathrm{gm}$. of NaCl . Unit-the gram calorie (at $15^{\circ}$ to $20^{\circ}$ ) per gram molecule. (See Thomsen, "Thermochemistry.")

[^9]
## ENERGY AND WAVE-LENGTH OF FULL RADIATION

The radiation from a full or black body radiator depends both in quality and quantity upon the temperature. The total energy radiated (of all wave-lengths), from unit area in unit time, is given by Stefan's law, $\mathrm{E}=\mathrm{K} \theta^{4}$, where K is Stefan's constant and $\theta$ is the absolute temperature (see Optical Pyrometry, p. 47, and below).

The dependence of the quality on the temperature is expressed by Wien's displacement law, $\lambda_{m} \theta=$ const., where $\lambda_{m}$ is the length of the particular waves which have maximum emissive power. Thus the emissive power $\mathrm{E}_{m}$ of the waves of length $\lambda_{m}$, varies as the 5 th power of the temperature (absolute) : $\mathrm{E}_{m} \theta^{-5}=$ const.

The emissive power of some particular wave-length $\lambda$ is expressed accurately by

$$
\mathrm{E}_{\lambda}=\mathrm{C}_{\lambda}-5 /\left(e^{a / \lambda \theta}-1\right) \cdots: \cdot \text { Planck's formula }
$$

where $C=353$ erg. $\cdot \mathrm{cm} .^{2} \mathrm{sec}^{-1}, a=1.43 \mathrm{I} \mathrm{cm} .-\mathrm{deg}$., and $e$ is the base of Napierian logs.
At low temperatures or for short wave-lengths ( $\lambda \theta<3 \mathrm{~cm}$.-deg.) Planck's formula becomes (to $.8 \%$ at least)-

$$
\mathrm{E}_{\lambda}=\mathrm{C}_{\lambda-5} e^{-a / \lambda \theta} \quad \therefore \text { Wien's formula (see p. 47) }
$$

For long waves and high temperatures ( $\lambda \theta>730 \mathrm{~cm}$. deg.), we have (to $\mathrm{I} \%$ at least) -

$$
\mathrm{E}_{\lambda}=\mathrm{C}^{-4} \theta_{c}-a / a . . . . \text { Rayleigh's formula }
$$

(See Preston's "Heat," 2nd edit. ; Kayser's "Spectroscopie," II. ; Lorentz's "Theory of Electrons," 1910.)

WIEN'S DISPLACEMENT LAW
$\lambda_{m} \theta=$ const. $=$ A. (See above). $\lambda$ is measured in cms.

## SOLAR CONSTANT AND TEMPERATURE OF SUN

The solar constant $S$ is the energy received from the sun by the earth (at its mean distance) per sq. cm . in unit time, corrected for the loss by absorption in the earth's atmosphere.

The determination of the absorption loss is difficult ; it is best derived from simultaneous observations at high and low stations.

Langley and Abbot ("Smithsonian Reports," 1903 et seq.) give the following relation between atmospheric absorption and wave-length :-

| Wave-length ( $\AA . \mathrm{U} .=10^{-8} \mathrm{~cm}$.) | 4000 | 6000 | 8000 | 10,000 | 12,000 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Fraction transmitted | 49 | 74 | 85 | -89 | '91 |

If R is the energy radiated in unit time from a sq. cm . of the sun's surface, then

$$
R=\left\{\frac{\text { earth's solar distance }}{\text { sun's radius }}\right\}^{2} \times S=\left\{\frac{9^{.28} \times 10^{7}}{4.33 \times 10^{0}}\right\}^{2} \times S=46,000 S
$$

Assuming the sun to be a full or black body radiator, its "effective" absolute temperature $\theta$ may be deduced either from (i) Stefan's law, $R=K\left(\theta^{4}-T^{4}\right)$, where $K$ is Stefan's constant (see above) and T is the earth's absolute temperature, or (2) Wien's displacement law, $\theta \lambda_{m}=$ const. (see above).

Langley and Abbot (ref. above) find the distribution of the energy of solar radiation among the different wave-lengths ( $\lambda$ ) to be as follows:-

| Wave-length ( $\AA . \mathrm{U}$.$) .$ | 400 | 4500 | 5000 | 5500 | 6000 | 7000 | 8000 | 10,000 | 12,000 | 14,500 | 21,000 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Relative energy, E. | $15 \%$ | 18.4 | 19 | 16 | 14 | II | 8.8 | $5 \cdot 4$ | 3.2 | 2 | 6 |

$\lambda$ for $\mathrm{E}_{\text {max }}=4900 \times 10^{-8} \mathrm{~cm}$. Taking Wien's displacement law to be $\theta \lambda_{\text {max }}=29$, and assuming the sun to be a full radiator, its temperature $\theta=5920^{\circ}$ absolute.

## SOLAR CONSTANT AND TEMPERATURE OF THE SUN (contd.)

The values of $S$ below are expressed in both (1) calories per min. per $\mathrm{cm} .{ }^{2}$, and (2) watts per $\mathrm{cm} .^{2}$ (I calorie per $\mathrm{sec} .=4.18$ watts). The sun's mean temp. $\theta$ is in degrees C. absolute. Abbot and Fowle find the solar constant varies by about $8 \%$. (See Poynting and Thomson's "Heat ; Chree, Nature, 82, 2090; Report (1910) of thie International Union for Solar Research ; and "Smithsonian Reports.")

$\dagger$ Calculated from S, taking Stefan's const. as $5.3 \times 10^{-12}$ watts $\mathrm{cm} .^{-2} \mathrm{sec} .^{-1} \mathrm{deg} .^{-4}$.

## THE CRYOSCOPIC CONSTANT

The cryoscopic constant, $K$, would be the depression of the freezing-point of a solvent when the molecular weight in grams of any substance (which does not dissociate or associate) is dissolved in 100 grams of the solvent, supposing the laws for dilute solutions held for such a concentration (Raoult, 1882). Van't Hoff (1887) showed that $K=R \theta^{2} /(100 L)$, where $R=$ the gas constant (see p. 5), $\theta$ the absolute freezing-point of the solvent, L its latent heat of fusion in ergs. Example.-For I gram-molecule of solute in 100 gms . of water-

$$
\mathrm{K}=8.315 \times 10^{7} \times\left(273^{.1}\right)^{2} /\left(79.67 \times 4.184 \times 10^{9}\right)=18.60
$$

(See Whetham's "Theory of Solution," p. 149.)

[^10]
## VELOCITY OF SOUND

The velocity of sound（longitudinal waves）in a body，$V=\sqrt{E / p}, E$ being the elasticity，and $\rho$ the density．In gases and liquids $E$ is the adiabatic volume elasticity；in isotropic solid rods or pipes E is Young＇s Modulus．For gases $\mathrm{V}=\sqrt{\gamma \mathrm{P} / \rho}, \mathrm{P}$ being the pressure，and $\gamma$ the ratio of the specific heat of the gas at constant pressure to that at constant volume．For values of $\gamma$ ，sce p． 58 ．

For moderate temperature variations，the velocity of sound in gases is given by $\mathrm{V}_{t}=\mathrm{V}_{0}\left(\mathrm{I}+\frac{1}{\frac{1}{2}} a t\right)=\mathrm{V}_{0}+6 \mathrm{I} t$ in cms ．per sec．for dry air $\left(\alpha={ }^{\circ} 00367\right)$ ．

The velocity of sound decreases with decreasing intensity down to the normal value．In gases in tubes the velocity increases with the diamter up to a limiting value for free space．The values below are for free space．Barton＇s＂Sound＂and Poynting and Thomson＇s＂Sound＂may be consulted．［r foot $=30.48 \mathrm{cms}$ ．］

## RATIO OF ELECTROMAGNETIC TO ELECTROSTATIC UNIT OF CHARGE

This ratio " $v$ " is a pure number, and is numerically equal to $\sqrt{\mu k}$, i.e. on Maxwell's theory, to the velocity of electric disturbances, such as light and Hertzian waves, through a medium whose magnetic permeability is $\mu$ and specific inductive capacity $k$ : (See pp. 7 and 84.) For the velocity of light, see above.

Most observers have used a "capacity method" of determining $v$. (See Gray, "Absolute Measurements; and Rosa, Bull. Bureau of Standards, 1907.)

## PHOTOMETRIC STANDARDS

The Geneva Congress of 1896 proposed a set of units for measuring ( 1 ) luminous intensity, (2) flux (the "lumen"), (3) illumination (the "lux "), (4) brightness, and (5) quantity of light (see Electrician, July 14, 1911). The British unit of intensity is the "candle." The mean spherical candlepower of a light is the mean of the intensities measured in all directions from the light. The mean horizontal candlepower is the mean of all the intensities in a horizontal plane through the lamp.

The British "candle" is a spermaceti candle, $\frac{7}{8}$ inch in diameter ( 6 to the lb.) which burns at the rate of 120 grains per hour. This is, however, found to be an unsatisfactory standard, and in modern photometry the British unit is taken as being one-tenth part of the light given out by the Harcourt io candlepower Pentane lamp, burning at a pressure of 760 mms . mercury in an atmosphere containing 8 parts in 1000 by volume of water-vapour as measured by a ventilated hygrometer. The candlepower of this lamp

=10+066(8-w)-008(760-H)
$$

where $w$ is the number of parts in 1000 (by vol.) of water-vapour in air at a barometric pressure of H mms. of mercury.

The United States "candle" prior to April 1, 1909, was $1.6 \%$ greater than the British:

The French unit is the Bougie decimale, which is the 20th part of the light given out by a sq. cm . of platinum at its solidifying point. This is a difficult unit to reproduce, and the Carcel lamp burning colza oil is used in practice. The Carcel unit is taken (with some uncertainty) as $4 \%$ less than the Bougie decimale.

The German unit is the light given out by the Hefner lamp (which burns amyl acetate), burning at a pressufe of 760 mms . mercury in an atmosphere containing 8.8 parts in 1000 (by vol.) of water-vapour as measured by a ventilated hygrometer.

The National Physical Laboratory, the Bureau of Standards of America, and the Laboratoire Central d'Electricité of Paris have come to an agreement which involves the reduction of the old value of the American candle by $16 \%$. They agree in future to employ as a common unit the proposed International candle = I British Pentane candle =1 American candle =1 French Bougie decimale = 10/9 German Hefner unit $=\cdot 104$ Carcel unit (see Paterson, Phil. Mag', 1909).

## EFFICIENCIES OF VARIOUS LIGHTS

It has become customary to express efficiencies (or rather inefficiencies) in watts per candle. The value of a luminous efficiency cannot be properly appreciated without a knowledge of the distribution of the intensity. Estimates of the proportion of light energy to the total energy vary widely. S. P. Thompson (" Manufacture of Light") quotes from I part in 7000 for a gas flame to $1 \%$ for the most efficient lights.

The usual accepted "efficiencies" are given below in watts per mean spherical candlepower. They must only be regarded as approximate (see Solomon, "Electric Lamps," 1908).

| Light. | Efficiency. | Light. | Efficiency. |
| :---: | :---: | :---: | :---: |
| Bat's-wing gas flame | c. 100 | Tantalum lamps | 1.7-2.1 |
| Paraffin lamps | c. 50 | Tungsten (osram, etc.) lamps | 13 |
| Welsbach mantle, etc. | c. 15 | Open arc lamps. | $\mathrm{I}^{1} \mathrm{I}-\mathrm{I}^{\circ} 4$ |
| High-pressure gas | c. 8 | Enclosed arc lamps. | $2 \cdot 3$ |
| Carbon filament lamps. | 3.5-4.5 | Yellow flame arc lamps | 4 |
| Metallized carbon filament lamps |  | Mercury vapour lamps. | 3-4 |
| Nernst lamps . | 2.1-2.4 |  |  |

In high-grade standard photometry the Lummer Brodhun photometer head is usually employed. A unit of light may be maintained and reproduced with an accuracy of the order of $\frac{1}{10} \%$, by means of sets of properly seasoned glow lamps.

The candlepower of a carbon glow lamp varies as the 6th power (approx.) of the voltage ; of a metallic filament lamp, as the 3.6 th power.

A candle is visible at about a mile on a clear dark night. The energy in the luminous radiation from a standard candle is about $5 \times 10^{5} \mathrm{ergs} / \mathrm{sec}$. (Rayleigh, "Collected Papers"), whence the energy falling on I sq. cm . at a distance of I metre would be 4 ergs per sec. Angström (1902) gets values about double these.

## 71 <br> GASEOUS REFRACTIVE INDICES

## GASEOUS REFRACTIVE INDICES AND DISPERSIONS

Dispersion.-Cauchy's equation is $\mu-\mathrm{I}=\mathrm{A}\left(\mathrm{I}+\mathrm{B} / \lambda^{2}\right)$, where $\mu$ is the refractive index for the wave-length $\lambda$; A and B are constants. $B$ is the coefficient of dispersion.

The refractivity $(\mu-1)=A$, when $\lambda=\infty$. The values of A and B are for wave-lengths measured in cms. The refractive indices are mostly for the sodium D line $\left(\lambda=5893 \times 10^{-8} \mathrm{~cm}\right.$.). The values of $\mu$ are reduced to a standard density at $0^{\circ}$ and 760 mms . by assuming that $(\mu-I) / \rho$ is a constant for each gas, $\rho$ being the density. Cauchy's formula is in general inadequate over large dispersions. (See Cuthbertson, Science Progress, 1908 ; and Proc. Eo Trans. lioy. Soc. for 1905 et seq.)

## REFRACTIVE INDICES

Refractive indices, $\mu$, (against air) at $15^{\circ} \mathrm{C}$. for various wave-lengths.
The temperature coefficient given below is the change of refractive index per $1^{\circ} \mathrm{C}$. rise of temperature for the case of the sodium $D$ line.

The refractive indices are due chiefly to Gifford (Proc. Roy. Soc., 1902, 1904, 1910); Rubens and Paschen (for the infra-red) and Martens (1902). The two Jena glasses are selected as typical. Other glasses are dealt with on p. 74 .

## SILVERING SOLUTION

Due to the late Dr. Common. Other recipes will be found in Baly's "Spectroscopy " (Longmans) and Woollatt's "Laboratory Arts" (Longmans).

Make up $10 \%$ solutions of (1) pure nitrate of silver, $\mathrm{AgNO}_{3}$; (2) pure caustic potash, KOH ; (3) loaf sugar ; and (4) ammonia ( $90 \%$ water, $10 \%$ ammonia of sp. gr. -880). To the sugar soln. add $\frac{1}{2} \%$ of pure nitric acid and $10 \%$ of alcohol. The sugar soln. is very much improved by keeping. Make up also a $1 \%$ soln. of $\mathrm{AgNO}_{3}$. Distilled water must be used for all the solns.

For silvering say a $12-\mathrm{in}$. mirror, take 400 c.c. of the $\mathrm{AgNO}_{3}$ soln. and add strong ammonia until the brown precipitate first formed is nearly dissolved, then use the $10 \%$ ammonia until the soln. is just clear. Add $200 \mathrm{c} . \mathrm{c}$. of the KOH soln. A brown precipitate is again formed, which must be dissolved in ammonia exactly as before, the ammonia being added until the liquid is just clear. Now add the I \% soln. of $\mathrm{AgNO}_{3}$ until the liquid becomes a light brown colour about equal in density of colour to sherry. This colour is important, and can only be properly obtained by the use of the weak soln. Dilute the liquids to 1500 c.c. with distilled water.

The mirror should be thoroughly cleaned with acid and placed in a dish of distilled water.

All being ready, add $200 \mathrm{c} . \mathrm{c}$. of the sugar soln. to $500 \mathrm{c} . \mathrm{c}$. of water ; add the mixture to the silver-potash soln., mix thoroughly, and pour them into a clean empty dish. Then lift the mirror out of its dish of distilled water and place it face downwards in this soln., taking care to exclude all air-bubbles.

The liquid will turn light brown, dark brown, and finally black. In four or five minutes, often sooner, a thin film of silver will commence to form on the mirror, and this will thicken until in about 20 minutes the whole liquid has acquired a yellowish-brown colour, with a thin film of metallic silver floating on the surface. Half an hour is the usual time taken in silvering, but this is shortened by using warmer liquids. About $18^{\circ} \mathrm{C}$. is the best temperature.

Lift the mirror out, thoroughly wash with distilled water, and stand on its edge for say 12 hours in an inclined position until it is dry. The slight yellowish "bloom" can then be polished off by rubbing softly with a pad of chamois leather and cottonwool. The subsequent polishing is done with a little dry well-washed rouge on the leather pad. The film should be opaque and brilliant, and with careful handling will be very little changed with long use.

Porcelain, glass, or earthenware dishes should be used.
If a very thick film is required, two silvering baths can be used, the article being left in the first bath for 15 minutes, then lifted out, rinsed with distilled water and at once immersed in the second bath, which should be ready in another dish. The film should not be allowed to dry during the operation of changing baths.

Note.-The silver-potash solution will not keep beyond a couple of hours. Any excess of this solution unused should have the silver precipitated at once with HCl . If the silverpotash is kept, say for 10 or 12 hours, a black powder collects on the surface. This powder, which is probably some form of fulminate of silver, is explosive, and may shatter the vessel.

## GLASS

The raw materials for the manufacture of glass are ( 1 ) silica-usually as sand or felspar; (2) salts of the alkali metals- $\mathrm{Na}_{2} \mathrm{SO}_{4}, \mathrm{Na}_{2} \mathrm{CO}_{3}$, or $\mathrm{K}_{2} \mathrm{CO}_{3}$; (3) salts of bases other than alkalies-red lead, limestone or chalk, $\mathrm{BaCO}_{3}$ or $\mathrm{BaSO}_{4}, \mathrm{MgCO}_{3}$, $\mathrm{ZnO}, \mathrm{MnO}_{2}, \mathrm{Al}_{2} \mathrm{O}_{3}, \mathrm{As}_{2} \mathrm{O}_{3}$, etc. In general, glasses rich in silica and lime are hard, while glasses in which alkali, lead, or barium preponderate are soft. Hardness is, of course, also largely dependent on annealing. Ordinary "soft" (i.e. easily fusible) German glass is a soda-lime glass rather rich in alkali; "hard" (refractory) glass is a potash-lime glass rather rich in lime. Jena combustion tubing is a borosilicate containing some magnesia.

Thermometry Glasses.-Glasses which contain both soda and potash to any extent give a large temporary zero depression (see p. 45). Data concerning Verre dur ( $7 \mathrm{I} \% \mathrm{SiO}_{2}, 12 \% \mathrm{Na}_{2} \mathrm{O}, \frac{1}{2} \% \mathrm{~K}_{2} \mathrm{O}, 14 \% \mathrm{CaO}, 2 \% \mathrm{Al}_{2} \mathrm{O}_{3}$ and MgO ), Fena $16^{\prime \prime \prime}$ $\left(67 \% \mathrm{SiO}_{2}, 14 \% \mathrm{Na}_{2} \mathrm{O}, 7 \% \mathrm{CaO}, 12 \% \mathrm{ZnO}, \mathrm{Al}_{2} \mathrm{O}_{3}\right.$ and $\left.\mathrm{B}_{2} \mathrm{O}_{3}\right)$, 7 ena $59^{\prime \prime \prime}\left(72 \% \mathrm{SiO}_{2}\right.$, $12 \% \mathrm{~B}_{2} \mathrm{O}_{3}, \quad 11 \% \quad \mathrm{Na}_{2} \mathrm{O}, 5 \% \mathrm{Al}_{2} \mathrm{O}_{3}$ ), Kew glass ( $44 \% \mathrm{SiO}_{2}, 34 \% \mathrm{PbO}, 12 \% \mathrm{~K}_{2} \mathrm{O}$, $2 \% \mathrm{Na}_{2} \mathrm{O}, 2 \% \mathrm{CaO}, \mathrm{MgO}$, etc.), will be found on p. 45 .

Optical Glasses.-In building up achromatic lens systems a knowledge of the dispersive power ( $\omega$ ) of each glass employed is essential. This is defined as the ratio of the difference of the deviations (i.e. the dispersion) for any two colours to the deviation of some mean intermediate colour. $\omega$ thus depends on the colours selected ; for visual work they are usually the red (C) line of hydrogen (wave-length $\lambda_{c}=6563 \times 10^{-8} \mathrm{~cm}$.), the yellow sodium (D) line ( $\lambda_{D}=5893$ ), and the green-blue (F) hydrogen line ( $\lambda_{\mathrm{F}}=4862$ ). If $\mu_{\mathrm{C}}, \mu_{\mathrm{D}}, \mu_{\mathrm{F}}$ are the corresponding refractive indices, $\omega=\left(\mu_{C}-\mu_{\mathrm{F}}\right) /\left(\mu_{\mathrm{D}}-1\right)$ for the brightest part of the visible spectrum.

Flint glass-a term which survives from times when ground flints were extensively employed in making the best glass-now always implies a dense glass which contains lead and has a high refractive index and dispersive power.

Crown glass, originally designating only lime-silicate glasses, is now applied generally to glasses having a low dispersive power.

Jena Optical Glasses.-For ordinary flints and crowns $\omega$ and $\mu$ are roughly proportional, and this was true for all commercially available glasses prior to the advances initiated in 1881 by Abbé and Schott at Jena. They succeeded (e.g. by the addition of barium) in producing glasses which do not obey any such proportionality ; e.g. the very valuable barium crown glasses (below) combine the high refractive index of a flint glass with the low dispersive power of a crown. Such glasses have brought.about the excellent achromatism and flatness of field which now obtain in photographic lenses and large telescopic objectives. The introduction of boron into a glass lengthens the blue end of the spectrum relatively to the red ; the addition of phosphorus, fluorine, potassium, or sodium has the opposite effect : such control over the dispersion has made the modern microscope possible.

Some typical examples of Jena glasses are subjoined. For a complete list, see the catalogue of Schott and Genossen, Jena. The simple phosphate and borate glasses have been withdrawn on account of their lack of durability. The borosilicate crowns are among the most durable and chemically resistant of all glasses. The U.V. glasses are markedly transparent to ultra-violet light as far as about $\lambda=2880$.

See p. 72, and Zschimmer's "History of the Jena Glass Works," Hovestadt's "Jena Glass," and Rosenhain's "Glass Manufacture," 1908 (with bibliography).
(After Zschimmer, Zeit. Inst., 1908.)

## SPECTROSCOPY

It is now agreed that the use of the diffraction-grating in fundamental work must be limited to interpolation between standard wave-lengths obtained by other means. The accepted standard lines are three in the spectrum of cadmium. Their wavelengths $(\lambda)$ obtained by interference methods, and measured (by direct comparison with the standard metre at Paris) in dry air at $15^{\circ} \mathrm{C}$. (H-scale) and 760 mms . mercury pressure, are given below in tenth-metres ( $=10^{-8} \mathrm{~cm}$. $=1$ Angström unit). (See Michelson's "Light Waves and their Uses.") $\left[\mu=10^{-4} \mathrm{~cm} . ; \mu, \mu=10^{-7} \mathrm{~cm}.\right]$

| Observer. | $\lambda \mathrm{Cd}$ red. | $\lambda$ cd green. | $\lambda$ cd blue. |
| :---: | :---: | :---: | :---: |

## STANDARD LINES-IRON ARC SPECTRUM

Obtained by an interference method, and based on Benoit, Fabry, and Perot's value for the wave-length of the red line of cadmium. The wave-lengths below are given in tenth-metres ( $10^{-8} \mathrm{~cm}$.), measured in dry air at $15^{\circ}(\mathrm{H}$-scale) and 760 mms . mercury. (Buisson and Fabry, Compt. Rend., 1907 and 1909.)

## CHIEF ABSORPTION (FRAUNHOFER) LINES IN SOLAR SPECTRUM

Rowland's wave-lengths corrected approximately by the use of Fabry and Perot's results, measured in tenth-metres ( $10^{-8} \mathrm{~cm}$.) in air at $20^{\circ}$ and 760 mms . Owing to atmospheric absorption, the sun's spectrum extends only to about wave-length 3000.

## EMISSION SPECTRA OF SOLIDS

For a fuller treatment of wave-lengths see Watts' "Index of Spectra" and appendices, Kayser's "Handbuch der Spectroscopie," Hagenbach and Konen's "Atlas of Emission Spectra," 1905. For recent work consult the Astrophysical Fournal. The wave-lengths below are measured in tenth-metres ( $10^{-8} \mathrm{~cm}$.) in air at $15^{\circ} \mathrm{C}$. and 760 mms . The visible spectrum colours are indicated $-r, 0, y, g, b, v$.

The brightest lines are emphasized and the approximate boundary of the ultraviolet region is indicated thus

## 77 <br> EMISSION AND ABSORPTION SPECTRA

## EMISSION SPECTRA OF GASES

The gases are all in vacuum tubes ( $2-4 \mathrm{mms}$. press.) ; only the brightest lines are given. The visible spectrum colours are indicated- $r, o, y, g, b, v_{0}$

See the general remarks on last page.

## ABSORPTION SPECTRA

For wave-lengths of the Fraunhofer lines in the sun's spectrum, see p. 75.
Among the enormous literature on absorption spectra, reference may be made to Kayser's "Handbuch der Spectroscopie," Baly's "Spectroscopy," Vogel's "Praktische Spectralanalyse," the writings of Prof. Hartley, Jones and Anderson's "Absorption Spectra of Solutions," 1909, Smiles' "Chemical Constitution and Physical Properties," and the British Association Reports of 1901 et seq.

Convenient substances which show good absorption spectra are-neodymium and praseodymium salts and didymium glass (which yield some extremely narrow absorption lines), iodine vapour, nitrogen peroxide, chlorine, chlorophyll, blood, and potassium permanganate solution.

## OPTICAL ROTATIONS OF PURE LIQUIDS AND SOLUTIONS

$\mathrm{A}_{t}=$ the rotation in degrees (for light of some given wave-length) of the plane of polarization by a liquid when at the temperature $t^{\circ} \mathrm{C}$.
$l_{t}=$ the length of the column of liquid in decimetres (i.e. 10 cms .).
$p=$ the number of grams of active substance in 100 grams of solution.
$q=(\mathrm{IOO}-p)=$ the percentage (by weight) of inactive solvent in the solution.
$\rho_{t}=$ the density in grams per c.c. of the liquid or solution at $t^{\circ}$.
$c_{t}=p p_{t}=$ the concentration expressed as grams of active substance ner 100 c.cs. of solution at $t^{\circ}$.
$[\alpha]_{t}=$ the specific rotation $\left(\right.$ at $\left.t^{\circ}\right)=\frac{\text { rotation per decimetre of sol. }}{\text { grams of active substance per c.c of sol. }}$
For a pure liquid $[a]_{t}=\frac{\mathrm{A}_{t}}{l_{t} p_{t}}$.
For an active substance in solution $[\alpha]=\frac{\mathrm{A}_{t}}{l_{t}} /\left(\frac{p}{p+q} p_{t}\right)=\frac{100 \mathrm{~A}_{t}}{l_{t} p p_{t}}=\frac{100 \mathrm{~A}_{t}}{l_{t} c_{t}}$, since $(p+q)=100$.

The rotation depends on the wave-length of the light used; it increases as the wave-length $(\lambda)$ diminishes $\left(\alpha \propto \frac{1}{\lambda^{2}}\right.$ approx. $)$. $\alpha$ also varies with the nature of the inactive solvent and with the concentration of the solution.

The rotation is called positive or right-handed (dextro, $d$ ) if the plane of polarization appears to be rotated in an anti-clockwise direction when looking through the liquid away from the source of light. The contrary rotation is called lævo (l). The molecular rotation is the specific rotation multiplied by the molecular weight.
$[\alpha]_{20}^{\mathrm{D}}$ indicates that the specific rotation is measured at $20^{\circ} \mathrm{C}$. using sodium (D) light.
(See Landolt's "Optical Rotations of Organic Substances and their Practical Application.")

## FARADAY EFFECT

## MAGNETIC ROTATION OF POLARIZED LIGHT

This effect was discovered by Faraday in 1845. The rotation per cm . per unit magnetic field-Verdet's constant, $r=\alpha /(\mathrm{H} l)$, where $\alpha$ is the rotation in minutes for the substance in a magnetic field of H gauss, and $l$ is the length of light-path parallel to the lines of force. $r$ varies with the temperature and is roughly inversely proportional to the square of the wave-length of the light used. Films of Fe , Ni , and Co are exceptions to this rule.

If the light is travelling with the lines of force (i.e. from N. to S.), then the direction of rotation is positive, if the plane of polarization is rotated clockwise, to an observer looking in the direction in which the light is moving. If the light is reflected back on its path, the rotation is increased.

The Molecular rotation $r_{m}=r \mathrm{M} / d$, where M is the molecular weight of the substance, and $d$ is its density. $r_{m}$ is an additive property in organic. compounds (Perkin, Fourn. Chem. Soc., 1884).

The rotations below are for the sodium D line ( $\lambda=5893 \times 10^{-8} \mathrm{~cm}$.).
(For Voigt's theory of magneto-rotation, see Schusters, "Optics," 1909. See also Becquerel's papers in Compt. Rend., etc.)

## DIOPTER

In applied optics the "power" of a lens or mirror is expressed in diopters. The number of diopters equals the reciprocal of the focal length expressed in metres.

## ELECTRICAL RESISTIVITIES

Electrical specific resistances or resistivities in ohmrecms. Conductivities (in reciprocal ohms) are the reciprocals of resistivitics. For a table of reciprocals, see p. 136 .

## METALS AND ALLOYS

The resistivity depends to some extent on the state of the metal. In geveral, cold drawing increases, while annealing diminishes the resistance. The winding of a wire into a coil increases its resistance.

For pure metals; the resistance is roughly proportional to the absolute temperature, and would apparently vanish not far from the absolute zero.. This rule does not hold even approximately for alloys.

For wire resistances, see p. 83 ; for temperature coefficients, next page. The thermal conductivities of the same samples of many of the substances below will be found on p .51 .

## ELECTRICAL RESISTIVITIES (contd.)

## NON.METALS AND INSULATORS

The resistivities are in ohm-cms. at room temperatures unless otherwise stated. The values for insulators naturally vary widely, and the figures below are merely typical and are probably, in many cases, nothing more than the resistances of the surfaces. For a discussion of some electrical insulators, see Kaye, Proc. Phy. Soc. Lond., 1911.

[^14]
## TEMPERATURE COEFFICIENTS OF RESISTANCE

To represent accurately over any considerable range the variation of electrical resistance (R) with temperature $(t)$ requires for almost all substances a parabolic or cubic equation in $t$. But if the temperature interval is not large, a linear equation $\mathrm{R}_{t}=\mathrm{R}_{0}(1+a t)$ may be employed; and this gives a definition of the mean temperature coefficient (a) over that temperature range. The table of resistivities above will readily yield the associated values of $\alpha$. The coefficients given below are average ones.

## STANDARD WIRE GAUGE

The sizes of wires are ordinarily expressed by an arbitrary series of numbers. There are, unfortunately, four or five independent systems of numbering, so that the wire gauge used must be specified. The following are English Legal Standard wire gauge values. (See Foster's "Electrical Engineers' Pocket Book.")

| Size. | Diameter. |  | S.ze. | Diameter. |  | Size. | Diameter. |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

## WIRE RESISTANCES

Average values in ohms per metre at $15^{\circ} \mathrm{C}$. The safe currents for copper (high conductivity annealed commercial) are calculated at the rate of about 270 $\mathrm{amps} . / \mathrm{cm} .^{2}$ for No. 12 wire, $430 \mathrm{amps} . / \mathrm{cm} .^{2}$ for No. 22 wire, and $500 \mathrm{amps} . / \mathrm{cm} .^{2}$ for smaller diameters. Larger current densities than these are allowed in the revised "Wiring Rules" of the Institution of Electrical Engineers. Eureka is practically identical with constantan.

The average temperature coefficient of resistance of copper is ${ }^{\circ} 00428$; of nickel, ${ }^{\circ} 0027$; of manganin, ${ }^{\circ} 00001$; of German silver, ${ }^{\circ} 00044$; of Eureka, - ${ }^{\circ} 00002$; of platinoid, ${ }^{\circ} 0025$ per degree Centigrade. The values for the alloys may vary considerably. The composition of manganin is $84 \mathrm{Cu}, 4 \mathrm{Ni}, 12 \mathrm{Mn}$; of German silver, $60 \mathrm{Cu}, 15 \mathrm{Ni}, 25 \mathrm{Zn}$; of Eureka, c. $60 \mathrm{Cu}, 40 \mathrm{Ni}$. Platinoid is said to be German silver with a little tungsten. For specific resistances, see p. 81.

## DIELECTRIC CONSTANTS

The inductivity, dielectric constant, or specific inductive capacity $k$ of a material mày be defined as-
(i) The ratio of the capacity of a condenser with the material as dielectric to its capacity when the dielectric is a vacuum.
(2) The square of the ratio of the velocity of electromagnetic waves in a vacuum to their velocity in the material. This ratio is dependent on the wave-length, $\lambda$, of the waves; in most cases $k$ increases with $\lambda$. Unless otherwise stated, the inductivities below are for very long waves $(\lambda=\infty)$ and at room temperatures.

If $\mu$ is the refractive index, then on Maxwell's theory of light, $k=\mu^{2}$, provided the frequency of the electrical oscillations is the same as that of the light vibratious. In practice we cannot find $k$ for vibrations as rapid as those of the visible rays; the alternative is to obtain (by extrapolation) the refractive index for waves of very great wave-length, e.g. by the use of Cauchy's formula, p. 71. When such data are available Maxwell's relation is found to hold fairly exactly in the case of a number of gases and liquids, though there are many substances which provide marked exceptions. :
$\cdots$ In general, a rise of temperature diminishes the inductivity. The temperature coefficient $\alpha$ between $t^{\circ}$ and $\mathrm{T}^{\circ}$ is defined by $k_{\mathrm{T}}=k_{t}\{\mathrm{I}-\alpha(\mathrm{T}-t)\}$. In the case of water Palmer (1903) finds that a increases slightly with the frequency of oscillation. The Clausins-Mossotti relation $\frac{k-1}{\rho(k+2)}=$ const. ( $\rho$ being the density) has been shown by Tangl (Ann. d. Phys., 1908) to hold from I to 100 atmos. in the case of $\mathrm{H}_{2}, \mathrm{~N}_{2}$, and air.

## IONIC DISSOCIATION THEORY

On the Dissociation Theory (Arrhenius, 1887), the solute is dissociated into electrically positive cathions and negative anions. For example, KCl in water exists as $\mathrm{KCl}, \mathrm{K}^{+}, \mathrm{Cl}^{-}$; sulphuric acid as $\mathrm{H}_{2} \mathrm{SO}_{4}, \mathrm{H}^{+}, \mathrm{H}^{-}, \mathrm{SO}_{4}^{++}, \mathrm{HSO}_{4}^{+}{ }^{-}$Probably, in many cases, these ions are attached to molecules of solvent. The degree of dissociation $\alpha=$ (number of dissociated solute molecules)/(total number of solute molecules). $\alpha$ is deduced from the osmotic pressure of the solution, and from its electric conductivity at different dilutions. The osmotic pressure is determined (1) directly, (2) from the raising of the boiling-point, and (3) from the depression of the freezing-point of the solvent by the presence of the solute. The equivalent conductivity ( $\Lambda$ ) for different concentrations of any difute solution is assumed to be proportional to the number of ions present. $\boldsymbol{\Lambda}$ approaches asymptotically a limiting conductivity ( $\Lambda_{\infty}$ ) for extreme dilutions, a state of things when, on this theory, the solute is completely dissociated. $\Lambda_{m} / \Lambda_{\infty}=a$ for the equivalent concentration $m$. The eathion and anion with their charges $+e$ and $-e$ (for monovalent ions) move in unit electric field in opposite directions with speeds or mobilities $u_{+}$and $u_{-}$. The electrolytic current also obeys Ohm's Law, so that $\mathrm{X}_{\kappa}=\left(u_{+}+u_{-}\right) n e$ (Kohlrausch, 1879), where X is the potential gradient in volts per cm ., $n$ the number of tive or -ive ions per c.c., $\kappa$ the conductivity of the solution in ohm $^{-1} \mathrm{~cm} .^{-1}$. This becomes $u_{+}+u_{-}=1 \cdot 037 \times 10^{-5} \Lambda \mathrm{~cm} . / \mathrm{sec}$., since $\kappa / n=\Lambda / \mathrm{N}$, and $\mathrm{N} e=96,740$ coulombs per gm. equivalent of ions.

The mobility of electrolytic ions has been directly observed by Lodge (1886), Whetham, Orme Masson, and D. B. Steele. The ratio $u_{-}\left(u_{+}+u_{-}\right) \equiv n$ is for the negative ion, the migration ratio or transport number of Hittorf (1853-9). $n$ can be determined, when complex ions are absent, from the change of concentration at the anode and cathode during electrolysis. The mobility of certain organic ions is approximately inversely proportional to their linear dimension a (Laby and Carse). The existence of this relation of Ohm's Law and of a relation between the viscosity $(\eta)$ of the solvent and the ionic mobilities (Kohlrausch, Hosking, and Lyle) indicates that the motion of the ion through the solution may follow Stokes' Law ( $v=\mathrm{F} / 6 \pi \eta \pi$, where F is the driving force), with the numerical constant, $6 \pi$, possibly changed.

The dissociation theory postulates the conditions existing in very dilute solutions. The role of the medium is rather neglected (Lowry, Science Progress, 1908). The dissociation should be large for a solvent with a high dielectric constant, for then the atiraction between the cathion and anion is small (Thomson and Nernst). This is generally true (Walden).
(Kohlrausch and Holborn, "Leitvermögen der Elektrolyten;" Whetham's "Theory of Solution.")

## MIGRATION RATIOS

Hittorf's migration ratio or transport number of the anion, $n=u_{-} /\left(u_{+}+u_{-}\right) ; m$ $=$ equivalent concentration per litre ; $t^{\circ}=$ temp. of observation.

## 86 CONDUCTIVITY OF SOLUTIONS

## ELECTRICAL CONDUCTIVITY OF SOLUTIONS

$\kappa_{18}=$ pecific electric conductivity (in ohms ${ }^{-1} \mathrm{~cm}^{-1}$ ) of the solution at $18^{\circ} \mathrm{C}$.
$p=$ mass of anhydrous solute per 100 gms . of solution.
$\eta=$ the number of gm . equivalents in i c.c. of solution. Gm. equiv. per litre $=1000 \eta$. To find $\eta$ note that $\kappa / \Lambda=\eta$.
$v=$ volume in litres containing one gm. equivalent of solute $=1 / 1000 \eta$.
$\Lambda=$ equivalent conductivity $=\kappa / \eta,=$ the conductivity in reciprocal ohms of 1 gm . equiv. in solution between electrodes 1 cm . apart. The chemical equiv. of, for example, " $1 / 2 \mathrm{CaCl}_{2}$ " is $111 / 2$.
Temp. coefficient $=\left(d_{\kappa} / d t\right) / \kappa_{18}$. (See Kohlrausch and Holborn, "Das Leitvermögen der Elektrolyten" (Teubner).) $\mathrm{K}=$ Kohlrausch ; $\mathrm{G}=$ Grotrian.

CONCENTRATED SOLUTIONS

STANDARD SOLUTIONS FOR CALIBRATING CONDUCTIVITY VESSELS
$\kappa_{18}$ for the purest water in a vacuum $=.04 \times 10^{-6} \mathrm{ohms}^{-1} \mathrm{~cm}^{-1}$ (Kohlrausch and Heydweiller) ; $\kappa_{18}$ for conductivity water in air is about $10^{-6} \mathrm{ohms}^{-1} \mathrm{~cm} .^{-1}$; KCl I $n=$ normal $\mathrm{KCl}=74.59 \mathrm{gm}$. /litre at $18^{\circ} \mathrm{C} . ; \mathrm{NaCl}$ sat. = saturated NaCl at temp. t. of experiment. Unit-ohm ${ }^{-1} \mathrm{~cm}^{-1}$. (See Kohlrausch, Holborn, and Diesselhorst.)

## ELECTROMOTIVE FORCES AND RESISTANCES OF CELLS

The E.M.F's given are for cells on open circuit, and are only approximate ; in the case of primary batteries they refer to freshly made up cells. The internal resistances quoted are only typical; they vary very widely in practice. With m niny primary cells the E.M.F. drops and the internal resistance increases as the cell ages. Nearly all modern dry cells are modified Leclanché batteries.
(See Slingo and Brooker's "Electrical Engineering.").

MAGNETIC INDUCTION

## 塁 = magnetic force <br> $\mathrm{E}=$ intensity of magnetization <br> $=$ magnetic moment per $\mathrm{cm} .^{3}$ <br> $=$ pole strength per $\mathrm{cm} .^{2}$

$13=$ magnetic induction, or flux density

B, W, and 5 are in lines per $\mathrm{cm}^{2}$, and are vector quantities.
Unit: $4 \pi$ lines start from unit magnetic pole.
$\mu=$ permeability $=13 /$ / $\mathbf{h}$. See p. 6.
$\mathrm{H}=$ susceptibility $=\mathrm{E} / \mathrm{K}_{\mathrm{G}}=(\mu-1) /(4 \pi)$. See p. 6.
Coercivity, $\exists_{\mathrm{m}}=0$, is the demagnetizing force required to make $33=0$ after saturation.
Coercive force is the demagnetizing force required to make $\overline{\mathfrak{b}}=0$ after some particular field strength.

Remanence, $\mathcal{B}_{H}=0$, is the induction remaining when the magnetic force is removed after some particular field strength.

The work done, i.e. hysteresis loss, $Q_{e,}$, in taking a $\mathrm{cm}^{3}$ of magnetic materiat through
 for the hysteresis loss is $\eta 13_{\text {max. }}^{n}$, where $\eta$ is a constant, and generally $\eta_{\xi}=1 \cdot 6$. The magnetic properties of a material depend not only on its chemical composition, but on its previous mechanical and heat treatment ; thus only general characteristics are indicated below.

Heusler alloys (discovered by Heusler in 1903) are composed of $\mathrm{Cu}, \mathrm{Mn}$, and $\cdot \mathrm{Al}$. They do not show the Kerr effect.

Good permanent magnet steel contains about $5 \% \mathrm{~W}$ and $6 \% \mathrm{C}$, is free from $\mathrm{Mn}, \mathrm{Cu}$, Ni , and Ti , and is hardened at $850^{\circ} \mathrm{C}$. (Hannack, 1909). Cast iron, chilled from $1000^{\circ} \mathrm{C}$., may also be used (Peirce and Campbell).

References.-Pure iron, Peirce, Amer. Four. Sci., 27 and 28, 1909; Terry, Phy: Rev., 1909; iron and manganese, Burgess and Aston, Phil. Mrag., 1909; Heusler alloys, Stephenson, Phy. Rev., 1910. (Ewing, "Magnetic Induction in Iron," and Kohlrausch, "Prakt. Phys."),

## MAGNETIC SUSCEPTIBILITIES OF THE ELEMENTS, ETC.

The susceptibility $\mathrm{H}=\mathrm{E} / \mathrm{z}$ 位 $=(\mu-1) /(4 \pi)$. $\mathrm{H}=0$ for a vacuum. The susceptibility depends very much on the purity of the material, especially upon the absence of iron. For pure elements II appears to be independent of $3 \boldsymbol{\xi}$, except possibly in the case of $\mathrm{Mg}, \mathrm{Sb}$, and $\mathrm{Ru} . \mathrm{H}$ is a periodic property of the atomic weight ; for example, $\mathrm{P}, \mathrm{As}, \mathrm{Sb}$, and Bi are comparatively strongly diamagnetic.

The values below are per grm. at $18^{\circ} \mathrm{C}$., except where some temperature is specified. The gases are per $\mathrm{cm}^{3}{ }^{3}$ at 1 atmos. [Honda (Ann. d. Phys., 19ro) used purest available materials and corrected -H for any traces of iron ; see also P. Curie, CEuvres, Paris, 1908.] + means paramagnetic ; -, diamagnetic.

## TEMPERATURE AND MAGNETIZATION

The magnetic moment ( $M$ ) of a magnet diminishes as the temperature ( $t$ ) rises. In $\mathrm{M}_{t}=\mathrm{M}_{\mathrm{o}}(\mathrm{I}-a t)$, a varies widely, but is of the order ${ }^{\circ} 0003$ to ${ }^{\circ} 001$. The permeability $\mu$ also depends on the temperature. There is a critical temperature' above which $\mu$ is very small; in the case of iron it is one of the recalescence temperatures, and is the same as for carbon steels containing up to $45 \%$ of C.

The critical temperature of a metal is not perfectly definite, but depends to some extent on whether the metal is being heated or cooled.

| Substance. | Crit. Temp. | Observer. | Substance. | Crit. Temp. | Observer. |
| :---: | :---: | :---: | :---: | :---: | :---: |

## TERRESTRIAL MAGNETIC CONSTANTS

Magnetic observatories no longer remain in large cities owing to electric tram disturbances, and thus many of the places for which reliable data exist are not generally known. The general locality of the station is indicated in many cases below.

Magnetic constants obtained in most physical laboratories are usually abnormal owing to the proximity of iron in some form.

Much of the data below is derived from the Reports of Kew Observatory, and the publications of the United States Coast and Geodetic Survey.

A W declination means that the N-seeking end of the magnetic needle points west of true north; a N inclination means that the same end of the needle points downwards.

H and V are the horizontal and vertical components of the earth's magnetic field.
(See Chree, "Terrestrial Magnetism," Encyc. Brit., 1 Ith edit., 1911.)

At the present period we are going through a remarkable secular atferation. For generations H had been steadily rising in Western Europe, but during the last few years a wave of depression has travelled across from the east. H has steadily fallen at Petrograd since about 1900, at Potsdam since about 1905, at Greenwich and Kew since 1907, while in 1909 H was still rising at Falmouth and Valencia: The easterly motion of the declination needle has also increased notably since 1900. Thus secular change data based on, say, the last five years will not serve to prospect the future.

## SPARKING POTENTIALS

-The sparking voltages given below are those which will break down non-ionized air at atmospheric pressure and room temperature. The electrodes are equal smooth polished metal balls of various diameters. Russell (Phil. Mag. $\boldsymbol{\sim}$ 1906) gives the dielectric strength of air at atmospheric pressures as between 38,000 and 39,000 volts per cm . for either direct or alternating potentials.
(See Kaye's "X Rays" (Longmans, 1916) for further values.)

## CATHODE DARK SPACE

The thickness $(d)$ of the Crookes dark space is given by $d=(\mathrm{A} / p)+\mathrm{B} / \sqrt{i}$, where $p$ is the pressure, $i$ the current density, and $A$ and $B$ are constants for each gas. This equation is satisfied very exactly by the ordinary elenientary gases, and a little less so by the gases of the helium group. Unfortunately for the use of the dark space as a ptessure indicator, the current density term in the formula is almost as large as the pressure term for pressures about $1 / 10 \mathrm{~mm}$.

The values of A and B below are for large plane aluminium electrodes. $d$ is measured in cms., $\phi$ in mms. of mercury. The unit of $i$ is $i / \mathrm{lo}$ milliampere per $\mathrm{sq} . \mathrm{cm}$. of cathode, which is about the sort of current density that obtains with an average coil discharge and a moderate-sized cathode.
(See Aston and Watson, Proc. Roy. Soc., 191r.)

## MOBILITIES OF IONS IN GASES

Velocities of ions are in cm . per sec. for unit field, or in $\mathrm{cm} .^{2} \mathrm{sec}^{-1}$ volt ${ }^{1}$ at temp. and press. of room. $\mathrm{K}_{+}=$mobility of positive ion, $\mathrm{K}_{-}$of negative.

For moist air (i.c. saturated with $\mathrm{H}_{2} \mathrm{O}$ ), $\mathrm{K}_{+}=\mathrm{r}^{\cdot} 37, \mathrm{~K}_{-}=\mathrm{I}^{\prime} 51$.
For dry air (dried by $\mathrm{CaCl}_{2}$ ), $\mathrm{K}_{+}=1 \cdot 36, \mathrm{~K}_{-}=1.87$. (Zeleny (air blast method), Phil. Trans., 1900.)

* $M$ ean $=\left(K_{+}+K_{-}\right) / 2$.

For mobilities of natural ions in air, see p. 105.

## IONIC MOBILITIES AT HIGH TEMPS

K in $\mathrm{cm} . \mathrm{sec}^{-1}$ per volt $\mathrm{cm} .^{-1}$ for coal-gas flames in most instances. The ionic mobility is independent of the acid of the salt. Gold's and Wilson's values for Kagree the best with existing theory, which makes $\mathrm{K}_{-}=\mathrm{Xe} \mathrm{\lambda} / \mathrm{mu}=17,000$ at $1800^{\circ} \mathrm{C}$. (Gold). X is the electric field per cm ., $\lambda$ is the mean free path, and $u$ the velocity of the corpuscle.

## CONDENSATION OF VAPOURS

Expansion $=v_{2} / v_{1}$, where $v_{1}$ is the volume of the gas before, and $v_{2}$ the volume after expansion. Supersaturation of the vapour (at end of cooling by expansion) necessary for condensation $=S=$ (density of vapour when drops are formed)/(density of saturated vapour at the same temp.). (See J. J. Thomson, "Conduction of Electricity through Gases.")

## e/m FOR NEGATIVE ELECTRONS

$\mathrm{e} / m$ in E.M.U. gm. ${ }^{-1}$. Velocities $v$ in $\mathrm{cm} . \mathrm{sec}^{-1}$. For some other values of e/m see J. J. Thomson's "Conduction of Electricity through Gases," and Wolz, A.d.P., 30, 274, 1909. The mean of Simon's, Becker's, Classen's, Kaufmann's, Wolz's, Bucherer's, and Bestelmeyer's values ise $/ \mathbf{m}_{0}=\mathbf{1} 7 \mathbf{7 2} \times \mathbf{1 0}^{7}$ E.M. U. $\mathbf{g m}_{\mathbf{m}^{-1}}$, where $m_{0}$ is the mass of the electron associated with very small velocities. For the variation of $e / m$ with velocity see p. 99. (See also Schuster, P.R.S., 1890.)

[^17] Rap. C.P., Rapports Congris à Taris; V.D.P.G., Verh. Deutschs. Phys. Gesell.

## ELECTRONIC e/m FROM ZEEMAN EFFECT

For a spectrum line of wave-length $\lambda$, which becämes normal triplet with a separation of $\delta \lambda$ in a magnetic field $H$ (in gauss, i.e. E.M.U.), Lorentz has shown that $e / m=2 \pi \mathrm{~V} \delta \lambda /\left(\lambda^{2} \mathrm{H}\right)$, where V is the velocity of light; $\mathrm{e} / \mathrm{m}$ is in E.M.U. gm. ${ }^{-1}$,
 with $e / m_{0}$ above.

## ELECTRONIC e/m AND VELOCITY

$m_{0}$ is the electromagnetic mass of the negative electron for infinitely small velocities, $m$ the transverse mass for a velocity $\eta ; \nu / V=\beta$, where $V$ is the velocity of light. (See Lorentz, L'Eclairage Électrique, July, 1905, and "The Theory of Electrons," 1909.) On the theory of Abraham (Gött. Nachr., 1902),

$$
\text { transverse mass } m=m_{03}\left(\frac{I+\beta^{2}}{2 \beta} \cdot \log \frac{I+\beta}{I-\beta}-1\right) / 4 \beta^{2}
$$

| $\beta$ | \| Infinitely small. | 0.1 | 0.5 | 0.9 | 0.99 | 0.999 | 0.9999 | 0.999999 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $m / m_{0}$ | 100 | 1015 | $1 \cdot 12$ | 181 | $3 \cdot 28$ | 4.96 | 6.68 | $10^{\circ}$ |

On the theory of Iorentz (Versl. Kon. Ac. Wet. Am., 1904) and the relativity theory of Einstein ( $A . d . P$., 1905), $m=m_{0}\left(1-\beta^{2}\right)^{-1 / 2}$. This theory has been confirmed by the experiments of Bucherer (A.d.P., 1909) and Wolz (ibid.), using $\beta$ rays from Ra with velocities from ( 9 to 2I) $\times 10^{9} \mathrm{~cm}$. per sec. Thus the mass of the negative electron is wholly electromagnetic.

| $\beta$ | $m / m$. | $\beta$ | $m / m_{0}$ | $\beta$ | $m / m{ }_{0}$ | $\beta$ | $m / m_{0}$ | $\beta$ | $\mathrm{m} / \mathrm{m} \mathrm{m}_{0}$ | $\beta$ | $m / m_{0}$ | $\beta$ | $m i m$ |

## RH AND v: MAGNETIC DEFLECTION

When negative rays of velocity $\tau$ are deflected by a uniform magnetic field $H$ (at right angles to their direction) into a circular path of radius R , then $\mathrm{RH}=$ $v m / e=v \phi(\beta) /\left(e / m_{0}\right)$, where $\phi(\beta)=\left(1-\beta^{2}\right)^{-\frac{1}{2}}$ on Lorentz's theory (see above), and $e / m_{0}=1 \eta 77^{2} \times 10^{7}$ E.M.U. gm. ${ }^{-1}$
v is in $10^{8} \mathrm{~cm}$. sec..$^{-1}$; RH in gauss cm . Example. If $\mathrm{RH}=1210$ gauss $\mathrm{cm} .{ }^{2}$, then $\mathrm{v}=174 \times 10^{8} \mathrm{~cm} . / \mathrm{sec}$.

[^18] Mag.; P.Z. Phys. Ze.t.

## a RAYS

## RANGE AND VELOCITY OF a RAYS

Range in cms. in air at 76 cm . and $t^{\circ} \mathrm{C}$. (see Bragg and Kleeman, Phil. Magr, 1905). Initial velocity ( $v$ ) in cms./sec. (Rutherford, Phil. Mag., 1906, 1907). Some of the velocities are calculated from the ranges of the a particles; RaC, ThC, and Polonium were observed. Energy of RaC a ray $=m v^{2} / 2=\frac{1}{2} v^{2} \cdot 2 e \cdot m / c_{\alpha}$ $=2006^{2} \cdot 10^{18} e /\left(5.07 \cdot 10^{3}\right)=8 \cdot 37 \cdot 10^{14} e=1 \cdot 3 \cdot 10^{-6} \mathrm{ergs}=3 \cdot 1 \cdot 10^{-13}$ calories. Loss of energy in air is proportional to path traversed : thus initial velocity of a particle $=$ (velocity of $\mathrm{RaC} \alpha) \times 347 \sqrt{ } / r+1 \cdot 25 \mathrm{~cm} . / \mathrm{sec}$., where $r$ is the range of particle. Also $v=1077 r^{-1} \beta^{3} \cdot 10^{9} \mathrm{~cm} . / \mathrm{sec}$. (Geiger, P.R.S., 1910)

## RELATIVE VOLUME IONIZATIONS FOR $\beta, \gamma$, AND $\times$ RAYS

Relative ionization $=\mathrm{I}_{r}=i \mathrm{P} / \mathrm{I} p$, where $i$ is the amount of ionization per unit volume for the gas at-a press. $p$, and I that for air at press. P, the other experimental conditions being the same. In the experiments with $\gamma$ rays (column headed $\gamma$ ), $\beta$ rays would also be present. Observers: for $\beta$ and $\gamma$ rays, Kleeman, P.R.S:, 1907 ; X rays, C., Crowther, P.C.P.S., 1909 ; P.R.S., 1909 ; Mc., McClung, P.M., 1904. Ir for secondary $\gamma$ rays is much the same as for X rays (see Kleeman, P.R.S., 190y).

For calculated total ionization when Röntgen rays are completely absorbed in various gases, see Crowther, Proc. Roy. Soc., 1909.

## HEATING EFFECT OF RADIUM

In calories per sec, per gm. of metallic radium with its radioactive products. E. von Schweidler and Hess, using 795 gm . Ra enclosed in 1 mm . glass +5 mm . Cu , obtained 0328 calorie $\mathrm{gm}^{-1}$ sec. ${ }^{-1}=118$ cals. $\mathrm{gm}^{-1} \mathrm{hr} .^{-1}$ The heating effect of a radioactive substance is proportional to the ionization it produces (Duane, Le Radium, 1909). The heat emission continues at temp. of liquid hydrogen (Curie and Dewar, 1903), and is mainly due to the kinetic energy of the a rays (Rutherford, "Radioactivity").

Temp. and press. have no effect on heat emission (Schuster, Eve, and Adams, Nature, 1907; Rutherford and Petavel, B.A. Rep., 1907 ; Schmidt, P.Z., 1908).

| Heat. | 4 Observer. - : | Heat. | Observer. |
| :---: | :---: | :---: | :---: |

Ber., 1903 | $\begin{aligned} & 25 \% \\ & 44 \% \\ & 31 \% \\ & .0325 \end{aligned}$ | $\left.\begin{array}{ccc} \text { Produced by } \mathrm{Ra} \\ " & , & \mathrm{Em}+\mathrm{RaB} \\ " & ., & \mathrm{RaC} \end{array} \right\rvert\, \begin{aligned} & \mathrm{R} . \& \mathrm{~B} . \\ & P . M ., \\ & 1904 \end{aligned}$ <br> Angström, P.Z., 1905 |
| .0306 | Rutherford and Barnes, Nature, 1903 ; P.M., 1904 | .0372 | Precht, A.d.P., 1906 <br> Schweidler and Hess, Wien. Ber., 1908 |

HEAT EMISSION FROM RaEm, AND THORIUM
The $6 \times 10^{-4}$ c.c, of RaEm (with its products) in equilibrium with 1 gm . Ra emit 75 of the 0328 calories emitted per sec. by the radium. Thus the total quantity of heat given out by i c.c. of RaEm during its whole life $=$ $75 \times: 0328 /\left(\lambda \times 6 \times 10^{-4}\right)=19 \times 10^{7}$ calories.

For old (mineral) thorium metal, the heat emitted is $5 \times 10^{-9}$ calories per sec. per gm. (Pegram and Webb, Phy. Rev., 1908).

## RADIUM EMANATION

$\Gamma$ is the period of decay (in days) to half initial activity. Taking $\mathbf{r}=3.66$ days, then the decay coefficient $\lambda=2^{1} 19 \times 10^{-6} \mathrm{sec} .^{-1}($ see p. 107).

| $\Gamma$ in days. | Observer, etc. | $\boldsymbol{r}$ in days. | Observer, etc: |
| :---: | :---: | :---: | :---: |
| $3 \cdot 77$ | Rutherford and Soddy, P.M., 1903. | $\begin{aligned} & 3.75 \\ & 3.58 \end{aligned}$ | Rümelin, ${ }^{\prime}$.M., r 907. For first 5 days. |
| $3 \cdot 88$ | Bumstead and Wheeler, A.7.S., 1904. | $\begin{aligned} & 3.75 \\ & 3.85 \end{aligned}$ | $\left\{\begin{array}{l}\text { During period } 5 \text { to } 20 \text { days. } \\ 20 \text { to } 40 \text { days' old emanation. }\end{array}\right.$ |

## DIFFUSION OF EMANATIONS

$D=$ coefficient of diffusion (in $\mathrm{cm} .^{2} \mathrm{sec} .^{-1}$ ) of the emanation into the gas stated at the pressure $p \mathrm{~cm} . \mathrm{Hg}$ and temp. $t^{\circ} \mathrm{C}$. indicated. According to J. J. Thomson (Nature, November 25, 1909): "D would only vary slowly with atomic weight," and not as the square root of the molecular weight of the emanation, as is assumed in the table below.

Russ finds $p \mathrm{D}=$ const. for AcEm. and for ThEm. Bruhat gives $p \mathrm{D} / \mathrm{T}^{2}$ $=$ const. for AcEm. between $0^{\circ}$ and $20^{\circ}$. (Molec. wgt. ThEm.)/(molec. wgt. AcEm.) $=142$ (Russ). Mol. wgt. of RaEm, $=222$ (Gray \& Ramsay, 1910).

B., Bruhat, Le Radium, 1909 ; B. \& W., Bumstead \& Wheeler, A.7.S., 1903; C., Chaumont, Le Radium, 1909 ; C. \& D., Curie \& Danne, C.R., 1903 ; D., Debierne, Le Radium, 1907 ; M., Makower, P.M., 1905; P., Perkins, A. $7 . S$. ; R., Russ, P.M., 1909, Le Radium, 1909; Ruth., Rutherford, "Radioactivity"; R. \& B., Rutherford \& Miss Brooks, C.N., 1902.

## Ra IN ROCKS

## EQUILIBRIUM ACTIVITIES IN MINERALS

Relative activity of radioactive products in minerals. Boltwood (A.F.S., April, 1908) found U 2.22 times as active as the Ra alone in minerals (see McCoy and Ross, A.7.S.).

| Product. | U | Io | Ra | RaEm. | Ras | RaB | RaC | RaF | Ac | Total. |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Relative activity. | 1 | $\cdot 34$ | $\cdot 45$ | 62 | 54 | 04? | 91 | 46 | $\cdot 28$ | $4 \cdot 64$ |

$3.4 \times 10^{-7} \mathrm{gm}$. Ra is in equilibrium with I gm. U (Rutherford and Boltwood, A.F.S., 1906). $7.3 \times 10^{6}$ gms. U equal in activity 1 gm . of $\mathrm{Ra}+$ its products to RaC . i.e. Ra just over 30 days old (corrected by Boltwood, A.7.S., 1908).

## RADIUM AND THORIUM IN ROCKS

Rutherford and Soddy (P.M., May, 1903) and W. E. Wilson (Nature, July, 1903) suggested that the heat liberated by radioactive changes is one of the sources of the Earth's heat. Thus the distribution of radium and thorium in the Earth's crust is of geophysical importance. Loss of heat from the Earth's surface $=$ temperature gradient $\times$ thermal conductivity of crust $\times$ area of Earth's surface $=(1 / 3200)$ $\times 004 \times 5.1 \times 10^{18}=6 \times 10^{12}$ calories per sec. Now, clementary radium in radioactive equilibrium (i.e. whole $U$ family) gives out $6 \times 10^{-3} \mathrm{cal} . / \mathrm{sec} . \mathrm{gm}$. (Rutherford $\S$ ), and therefore $I^{1} 1 \times 10^{14} \mathrm{grms}$. of radium, or $10^{14} / \mathrm{IO}^{27}=10^{-13} \mathrm{gm}$. per c.c., throughout the Earth's volume would maintain it at a steady temperature. Thorium contributes $5 \times 10^{-9} \mathrm{cal}$. $/ \mathrm{sec} . \mathrm{gm}$. The total heating effect in calories per gram of rock per hour is for the lava indicated below by *, $30 \times 10^{-10}$; and for the rock indicated by $\dagger, 2.9 \times 10^{-10}$; for average igneous rock, $11 \times 10^{-10}$.
(See Strutt, Proc. Roy. Soc., I G06-7; Joly, "Radioactivity and Geology," 1909.)

Extent :- ${ }^{1} 50,{ }^{2} 2 \cdot 5,{ }^{3} 51$ million square miles. $\dagger 1000$ feet below the surface. § Assuming that the heat due to each member of the family is proportional to the ionization it produces. || Preliminary result. B., Blanc., P.M.; F.M., Eve and McIntosh, P.M.; F.F., Farr and Florance, P.M.; Fl., Fletcher; J., Joly, P.MI.; S., Strutt (above). A. F.S., Amer. Fou;n. Sci.; P.M., Phil. Mag.

ELECTRIC ARC

## RADIUM IN SEA-WATER

In grams per gram of sea-water. Deduced from the observed amount of Ra Em.

| Amount. | Place. | Observer. | Amount. | Place. | Observer. |
| :---: | :---: | :---: | :---: | :---: | :---: |

## MOBILITIES OF NATURAL IONS IN AIR

Mobility or speed K is in $\mathrm{cm} .^{2}$ sec..$^{-1}$ volt ${ }^{-1}$ at room temperature and $76 . \mathrm{cm}$. (see p. 95). The ions are named from their velocities: the small ions are assumed to have the velocity of X-ray ions. (See Pollock, Science, 1909 ; Eve, Phil. Mag., 19, 1910; Lusby, Proc. Camb. Phil. Soc., 1910.)

| Ion. | Mean $\mathbf{X}$. | Observer. | Ion | Mean $\mathbf{X}$. | Observer. |
| :---: | :---: | :---: | :---: | :---: | :---: |

* Humidity, 19 grms. $\mathrm{H}_{2} \mathrm{O}$ per cubic metre. +5 grm. $\mathrm{H}_{2} \mathrm{O}$ per cubic metre of air. Pollock, Austl. Ass. Adv. Sci., 1908.

## ELECTRIC ARCS

Mrs. Ayrton's formula for carbon arcs, $\mathrm{E}=\alpha+\beta l+\frac{\gamma+\delta l}{i}$, has been shown by Guye and Zébrikoff (Compt. Rend., 1907) to hold for short stable arcs between metals. E is the voltage across the arc, $i$ is the current in amperes, and $l$ the length in mms. of the arc in air at atmospheric pressure. Mrs. Ayrton's formula does not hold for very long arcs, nor for cored carbons. For stability, an arc requires an external resistance $R$ which must be less than $\frac{\left\{E_{x}-(\alpha+\beta l)\right\}^{3}}{4(\gamma+\delta l)}$ ohms, where $E_{x}$ is the total available voltage ; or $\mathrm{E}_{x}$ must exceed $a+\beta l+2 \sqrt{\mathrm{R}(\gamma+\delta l)}$. If R is too small the arc hisses, in which case the current is independent of the voltage across the terminals. The constants for carbon refer only to the particular șizes and quality used by Mrs. Ayrton.
(See J. J. Thomson, "Conduction of Electricity through Gases.")

## ATOMIC AND RADIOACTIVITY CONSTANTS

References: J. J. Thomson's "Conduction of Electricity through Gases," Rutherford's "Radioactivity," H. A. Lorentz, Eclairage Electrique, 44, 1905, "Theory of Electrons," 1909, Jeans' "Dynamical Theory of Gases," and Millikan, P.M., 1917.

Heat given out by 1 gm . of metallic radium with its products
Number of a particles emitted by I gm. radium without products
Initial velocity of a particle from RaC
Initial energy of $a$ particle from $\mathrm{RaC}=m v^{2} / 2=v^{2} e$ $/\left(2 e / m_{\alpha}\right)=2.06^{2} \cdot 10^{18} \times 1.57 \cdot 10^{-20} /\left(2 \times 507 \cdot 10^{3}\right)$
Total number of ions produced in air by an a ray ( RaC )
Volume of helium at $0^{\circ}$ and 76 cm . produced by 1 gm. radium
Calculated volume $=4 \times$ number of $a$ rays emitted $/ \mathrm{N}$ $=4 \cdot 3 \cdot 4 \cdot 10^{-9} / 2 \cdot 75$
Number of $\beta$ particles emitted per sec. by the RaC in equilibrium with 1 gm . Ra (Makower, Phil, Mag., 1909)

## CONSTANTS OF RADIOACTIVE SUBSTANCES

Atomic weights: $\mathrm{O}=16, \mathrm{U}=238^{\circ} 2, \mathrm{Ra}=226{ }^{\circ} 0, \mathrm{Th}=232^{\circ} 4^{\circ}$.
Rate of decay; If I is the radioactivity of a substance at a time $t$, then $\mathrm{I}=\mathrm{I}_{0} e^{-\lambda t}$, where $\mathrm{I}_{0}$ is the initial activity when $t=0$. $\lambda$ is given below in sec. ${ }^{-1}$. If $\Gamma$ is the period in which the activity decreases to half its initial value (i.e. $1 / I_{0}=\frac{1}{2}$ ), then $\lambda=69315 / \mathrm{r}$ sec. ${ }^{-1} . \quad \mathrm{r}$ is given below in secs. (s.), mins. (m.), hrs. (h.), days (d.), or years (y.).

Coefficients of absorption $\Lambda$ are given in $\mathrm{cm} .^{-1}$ for $\beta$ rays in Al foil and for $\gamma$ rays in lead foil. If $\mathrm{J}_{0}$ is the intensity of the rays incident un foil of thickness $d \mathrm{~cm}$., and J is the intensity of the emergent rays, then $\mathrm{J}=\mathrm{J}_{0} e-d \Lambda$.
(See Rutherford's "Radioactive Substances," Camb. Univ. Press, and Wendt. Phy. Rev., 1916, for a complete table.)

PROPERTIES OF RADIOACTIVE SUBSTANCES

| Subotance. | Properties. | Substance. | Properties. |
| :---: | :---: | :---: | :---: |
| Rad.U | Sol. in excess of am. carb. Nitrate soluble in ether and acetone. <br> Carried down by $\mathrm{BaSO}_{4}$ and ferric hydrate. Soluble in HCl . |  | Carried down by $\mathrm{PbCO}_{z}$ and by $\mathrm{SnCl}_{2}$ with Hg and Te. RaD, $\mathrm{E}_{1}, \mathrm{E}_{2}$, and F can be separated by electro lysis. |
| ס. x | Less volatile than U. Volatile in electric arc. Insoluble in excess of am. carb. Soluble down by barium | Ac | Produces helium. Precipitated by oxalic acid in acid solutions. Oxalate insoluble in HF ; accompanies |
|  | by moist ferric hydrate, and by animal charcoal. | Rad.Ac | Slightly volatile at high temps. Insoluble in $\mathrm{NH}_{4} \mathrm{OH}$. |
|  | Soluble in excess of am. oxalate. Carried down by $\mathrm{H}_{2} \mathrm{O}_{2}$ in presence of U salts. |  | trolysis, by fractional precipitation, by ammonia, and by animal charcoal. |
| Ra. | Characteristic spectrum. Spontaneously luminous. Analogous to Ba . $\mathrm{RaCl}_{2}$ and | Acx | Deposited by electrolysis in alkaline solution. Not precipitated by $\mathrm{NH}_{4} \mathrm{OH}$. |
|  | $\mathrm{RaBr}_{2}$ are less soluble than $\mathrm{BaCl}_{2}$ and $\mathrm{BaBr}_{2}$. | AcEm. | Behaves as inert gas. Coef. of diffusion in air 0.1I. |
| E.aEm. | One of group of inert gases. Characteristic spectrum. Coef. of diffusion in air $=$ $0^{\circ} \mathrm{I}$ (see p. 103). Mol. wt. $=218$. | Aca | Condenses at $-120^{\circ} \mathrm{C}$. <br> Volatile below $400^{\circ} \mathrm{C}$ <br> Soluble in $\mathrm{NH}_{4} \mathrm{OH}$ and strong acids. |
| RaA Rab | Behaves as a solid. Deposited on cathode in an electric field. Volatile at $800-900^{\circ} \mathrm{C}$. Soluble in strons acids. | ACB | Volatile below $700^{\circ} \mathrm{C}$. Soluble in $\mathrm{NH}_{4} \mathrm{OH}$ and strong acids. Deposited by electrolysis of active denosit on |
| Rab | Like RaA. Volatile at $600-$ $700^{\circ} \mathrm{C}$. Precipitated by |  | lusis of active deposit on the cathode in HCl. |
| Rad | BaSO4. <br> Physically like RaA. Vola. tile at $800-1300^{\circ} \mathrm{C}$. Chemically, like RaB. Deposited on Cu and Ni . Carried | Th | Volatile in electric arc. Colourless salts not spontaneously phosphorescent. Salts pptd. by $\mathrm{NH}_{4} \mathrm{OH}$ and oxalic acid. |
|  | down with precipitated copper. Perhaps a mixture of 2 or 3 products. | Rad.Th | Carried down by hydrates, precipitated by $\mathrm{NH}_{4} \mathrm{OH}$. |
| Rad | Volatile below $1000^{\circ} \mathrm{C}$. Soluble in strong acids. Reactions analogous to those of Pb . | ThX | Soluble in $\mathrm{NH}_{4} \mathrm{OH}$. Carried down by iron. Deposited by electrolysis in alkaline soln. |
| RaE ${ }_{1}$ | Volatile at red heat. Soluble in cold acetic acid. Reactions analogous to those of Pb. | ThEm. | Inert gas. Condenses just above $-120^{\circ} \mathrm{C}$. Coefficient of diffusion in air $=\cdot 10$. |
| RaE ${ }_{2}$. | Not volatile at red heat. Reactions analogous to those of bismuth. | Tha | Volatile under $630^{\circ} \mathrm{C}$. Soluble in strong acids. <br> Volatile below $730^{\circ} \mathrm{C}$ Like |
| $\boldsymbol{R a F} \mathbf{F}$ POII) | Volatile towards $1000^{\circ} \mathrm{C}$. Deposited from its solutions on $\mathrm{Bi}, \mathrm{Cu}, \mathrm{Sb}, \mathrm{Ag}, \mathrm{Pt}$. | ThC | ThA. Deposited on Ni. Separated from Tha by electrolysis. Like ThB. |

## PHYSICAL CONSTANTS OF CHEMICAL COMPOUNDS

For properties of the elements, see : density, p. 20; melting and boiling points, p. 48 ; solubility in water, p. 124. Metallo-organic compounds are given under "Organic Compounds," p. 118.

Formulæ.-Hydrated forms (which are often crystalline) are indicated thus: $\mathrm{CaI}_{2}\left(\right.$ and $\left.+6 \mathrm{H}_{2} \mathrm{O}\right)$; the properties given are for the anhydrous substance.

Formula (Molecular) Weights are calculated with atomic weights for 1911 (p.1).
Densities.-When no temp is given, grams. per c.c. at $15^{\circ}$ may be assumed. When preceded by "A" the density is relative to that of air ("OoI293 gram per c.c. at $0^{\circ}$ and 760 mms .). To convert this into a density relative to $0=16$, multiply by 14.47. For those gaseous densities known with accuracy, see p. 26. Other densities on pp. 20-26.

Melting and Boiling Points are for anhydrous substances at 760 mms . mercury unless some other conditions are specified. $T=$ temp. of transition or pseudo"melting" point of hydrated substance. For fats and waxes, see p. 50.

Solubilities are given as grams of substance in 100 grams of water at the temp. stated. " $p$ " indicates grams per 100 grams of solution. "V" means volumes of substance at $0^{\circ}$ and 760 mms . per 100 volumes of water at the temp. stated. "Soluble" infers solubility in either hot or cold water; "insoluble" indicates solubility in neither. (See also pp. 124, 125.)

For more complete tables, see Van Nostrand's "Chemical Annual" and Biedermann's "Chemiker-Kalender" for current year; Dammer's "Handbuch der Anorganischen Chemie;" Beilstein's "Handbuch der Organischen Chemie;" Watts' "Dictionary of Chemistry;" and F. W. Clarke's "Specific Gravities."

## INORGANIC COMPOUNDS

Formula, formula (molecular) weight, density, melting and boiling points, and solubility in water.

## ELECTROCHEMICAL EQUIVALENTS

Faraday's laws of electrolysis are expressed by $m=i z t$, where $m$ is the mass in grammes of an ion liberated in $t$ secs. by a current of $i$ amperes; $z$ is the electrochemical equivalent of the ion, i.e. the mass liberated by 1 ampere in 1 second.

The exactness of Faraday's laws is obscured in many cases by secondary chemical reactions, and the values of the different electrochemical equivalents are practically always derived by calculation from that of silver, which has been accurately determined (see p. 8). Electrochemical equivalents are proportional to chemical equivalents.

Chemical equivalent $=\frac{\text { atomic weight of element }}{}$
$=\overline{\text { valency of element for electrolyte used }}$

## GASES IN WATER

S indicates the number of c.cs. of gas measured at $0^{\circ}$ and 760 mms . which dissolve in I c.c. of water at the temperature stated, and when the pressure of the gas plus that of the water-vapour is 760 mms .

A indicates the same, except that the gasitself is at the uniform pressure of 760 mms , when in equilibrium with the water. (For other values, see p. 109.)

## MUTUAL SOLUBILITIES OF LIQUIDS

The data for the uppermost layer of the two solutions in equilibrium are given in the first line in each case. The pressure in some cases exceeds one atmosphere. Numbers are grams per roo grams of solution. (From data in Seidell's "Solubilities.")

## SOLUBILITIES OF SOLIDS IN WATER

$s=$ number of grams of anhydrous substance which when dissolved in 100 grams of water make a saturated solution at the temperature stated.
$p=$ no. of grams of anhydrous substance per 100 grams of saturated solution.
The formula given is that of the solid phase which is in equilibrium with the solution. (See Seidell's "Solubilities," New York, 1907, where the most complete and accurate.data will be found for solubilities.) For other solutions, see p. IO9.

GRAVIMETRIC FACTORS

## FACTORS FOR GRAVIMETRIC ANALYSIS

Calculated with atomic weights for 1911 (p. 1).
Example:-1 gram $\mathrm{Al}_{2} \mathrm{O}_{3}$ is chemically equivalent to 5303 gram Al , or 1 gram Al is equivalent to $1 / 5303 \mathrm{Al}_{2} \mathrm{O}_{3}$. A table of reciprocals is given on p. 136 .
(See Van Nostrand's "Chemical Annual," London.).

[^0]:    * Beryllium or Glucinum (GI).
    $\dagger$ Niobium or Columbium (Cb).
    The following atomic weights for 1911 (see pp. 109, 127) include only those which have been subsequently changed:-
    $\mathrm{Ca}, 40.09$; C, 12.00 ; Er, 167.4 ; IIe, 3.99 ; $\mathrm{Fe}, 55^{.85}$; Kr, 829 ; $\mathrm{Pb}, 207.10$; $\mathrm{Lu}, 174^{\circ} \mathrm{O} ; \mathrm{Hg}, 200^{\circ} \mathrm{O} ; \mathrm{Pr}, 140^{\circ} 6 ; \mathrm{Ra}, 226^{\circ} 4 ; \mathrm{S}, 32^{\circ} 07$; $\mathrm{Ta}, 181^{\circ} \mathrm{O} ; \mathrm{Th}, 232^{\circ} \mathrm{O}$; $\mathrm{Sn}, 119^{\circ} 0 ; \mathrm{U}, 238^{\circ} 5 ; \mathrm{V}, 51^{\circ} 06 ; \mathrm{Yb}, 172^{\circ} \mathrm{O} ; \mathrm{Y}, 89^{\circ} \mathrm{O}$.

[^1]:    * According to the latest estimates, the mean meridian quadrant $=10,002,100$ metres (see p. 13).
    $\dagger$ Tidal friction is retarding the rotation of the earth, so that the above (sidereal) definition of the second, while practically justificd, is theoretically not quite perfect.
    $\ddagger$ The first point of Aries is that one of the two nodes of intersection of the ecliptic and the celestial equator where the sun (moving in the ecliptic) crosses the equator from south to north (at about March 21). The ccliptic is the apparent yearly track of the sun in a great circle on the celestial sphere.
    § Neglecting small irregularities, this is true also for any star.

[^2]:    * Mean of Helmert and U.S. Survey.
    $\dagger$ Using Boys' and Braun's result for density.

[^3]:    * This is the angle subtended by the semi-diameter at a distance equal to the Earth's miean distance from the Sun.
    $\dagger$ The inclination of the plane of the Sun's equator to the plane of the ecliptic.
    $\ddagger \mathrm{D}$ means direct ; R , retrograde.
    § The ellipticity $=(a-b) / a$, where $a$ is the major axis and $b$ the minor axis of the spheroid of revolution. The value given for the Earth is-Helmert's (p. $\ddagger$ ) $)$

    II Perihelion is the point in the orbit nearest the Sun. Lungitude is the angular distance from the first point of Aries (see p. 3), measured along the ecliptic.

    I A node is one of the two points at which a planet's orbit intersects the plane of the ecliptic. At the ascending node the planet passes from south to north of the ecliptic.
    ** The eccentricity $=\sqrt{\left(a^{2}-b^{2}\right)} / a$, where $a$ and $b$ are the major and minor axes of the orbit.

[^4]:    * Grindley and Gibson.

[^5]:    * Extrapolated.
    + The vapour pressures here given have been graphically interpolated from the observers' values. B., Bodenstein ; C., Callendar ; D., Dewar ; F., Faraday ; K., Kahlhaum ; M., Macisintosh ; R., Regnault ; Ra. and Y., Ramsay and Young ; Ri., Richardson ; S., Schmidt ; Y. and T., Young and Thomas.
    $\ddagger$ Triple point.

[^6]:    *These constants are not suitable for temperatures below $300^{\circ}$. $\dagger$ Eureka, $60 \mathrm{Cu}, 40 \mathrm{Ni}$.

[^7]:    * See section on thermo-electric thermometers, p. 46, for meaning of $(a)$ and (b).
    $\dagger$ In reducing atmosphere; $995^{\circ}$ in air. $\ddagger$ Const, vol. N. thermometer.

[^8]:    * See Guillaume's "Les Applications des Aciers au Nickel," 190+. + Invar is obtainable in three qualities, with a range of coefficients of $(-3$ to +2.5$) \times 10^{-6}$ at ordinary temperatures. $\ddagger$ Used for international prototype metre (see p. 3). § Used for Imperial Standard Yard (see p. 4). B. Benoît; Bd. Bedford; C. Chappuis; D. Dittenberger; Dl. Daniell ; F. Fizeau; H. Hagen ; H.D. Holbom and Day ; H.G. Holborn and Griineisen; M. Matthiessen ; N.P.L. National Physical Laboratory ; Pf. Pfaff; R. Randall. Ru. Russner ; S. Scheel ; Sc. Schott; Sm. Smeaton; St. Stadthagen; T. Tutton; T.S.S. Thiesen, Scheel, and Sell ; V. Voigt ; V1. Villari ; Vn. Vincent.

[^9]:    * Heat developed on diluting $\mathrm{NH}_{3} \cdot n \mathrm{H}_{2} \mathrm{O}$ to $\mathrm{NH}_{3} \cdot 200 \mathrm{H}_{2} \mathrm{O}$ (Berthelot).

[^10]:    * Mean of six observers ; A.R., Ampola and Rinnatori, 1897 ; B., Berthelot; C., Colson; E., Eykman, 1889 ; F., Fischer; G., Griffiths (who used 0.0005 to o.02 normal sugar solutions) ; L., Lespieau, 1894; P., Paternó, 1889 ; Pe., Pettersson ; P M., Paternò and Muntemartini, 1894 ; P.W., Pettersson and Widman ; R., Raoult; T., Tolloczko, 1899.

[^11]:    * White light. † Violet light. $\mu=\mathrm{r} 00205$ for red light. Iodine shows anomalous dispersion. C. \& M., Cuthbertson \& Metcalfe ; P. \& M.; Prideaux \& Metcalfe.

[^12]:    * Langley, 1900.
    $\ddagger$ Oxygen in earth's atmos.
    $\dagger$ Emission line in chromosphere alone.
    § Wood, 19II. || X and $\gamma$ rays 8.4 to 00\%.

[^13]:    * The molecular weight of cane-sugar is 342 ; which, after conversion to invert sugar, becomes 360. Hence the new concentration of the invert sugar solution is $\frac{36}{34} c$, where $c$ is the number of grams of cane-sugar in 100 c.cs. of the original solution.

[^14]:    * National Physical Laboratory.
    $\dagger$ Phillips.
    $\ddagger$ In dark.
    § Wick, 1908.

[^15]:    * High conductivity annealed commercial. $\quad+\mathrm{R}_{t}=\mathrm{R}_{0}\left(\mathrm{I}+{ }^{\circ} \mathrm{O}_{3} 88 t+{ }^{\circ} \mathrm{O}_{5} t^{2}\right)$-Smith (N. P. L.), 1904. $\ddagger$ N. P. L. § Most samples of manganin have a zero temp. coeff. at from $30^{\circ} \mathrm{C}$. to $40^{\circ} \mathrm{C}$.
